## 1.0 Introduction

This document is the NRAO’s final report for the work completed for “ALMA Band 1 Receiver Development Study”

### 1.1 History

The Band 1 consortium, consisting of ASIAA, HIA, the University of Chile, and the NRAO in February of 2012 jointly submitted a proposal for North American ALMA Development funding for “ALMA Band 1 Receiver Development Study”.

### 1.2 Scope

The scope of the NRAO’s involvement in the Band 1 ALMA development project is consistent with the “List of Deliverable” in Section 5 of the development proposal and included the following:

1. Modify existing Q-Band LNA designs to operate from 35 to 50 GHz, then build and measure a prototype.
2. Provide design concepts for a room temperature single-sideband down converter to translate the 35-50 GHz RF range to an IF between 4 and 12 GHz.
3. Provide costing for a Band 1 local oscillator system that incorporates the same design guidelines as used in the other 8 local oscillators provided to the ALMA project.
4. Design, build, and measure an orthogonal mode transducer (OMT) by scaling the NRAO’s existing 12 to 18 GHz designs to operate from 35 to 50 GHz
5. Provide pricing for the manufacture of cartridge bias supply modules which are identical to the existing ALMA designs used for the other eight existing ALMA cartridges.
6. Provide systems engineering labor to develop a set of preliminary specifications.

Technical details and costing for each of these items was provided to the Band 1 consortium during the Band 1 down-selection meeting held in Taipei in January of 2013.

## 2.0 Science Contributions

Brian Mason contributed the following section to the Band 1 science case, which is now on the arXiv preprint server. It is a substantial reworking and augmentation of the original SZ science case, and included adding results of ALMA simulations. He also contributed to the analysis of the relative strengths of ALMA and JVLA which is in that final document.

Much of what we know about galaxy clusters has come from x-ray observations of thermal bremsstrahlung emission of the intra-cluster medium (ICM)-- the angular resolution of Chandra, for example, has been crucial to advancing our understanding in this area and has resulted in a renaissance in astrophysical studies of galaxy clusters. In recent years the Sunyaev-Zel'dovich Effect (SZE) has provided an increasingly important view of these cosmic structures (Birkinshaw 1999). Since the SZE signal is proportional to the product of the electron density and its temperature ( $\sim n_e T$  compared to  $n_e T^2$  for the x-rays) it gives a complementary view of the physical state of the ICM, more sensitive to hot phases and directly measuring local departures from thermal pressure equilibrium. To date the majority of SZE observations have been carried out at comparatively low angular resolution (beams  $>1'$  in size), yielding information about the overall bulk cluster properties. Advances in instrumentation have begun making higher angular resolution measurements of the SZE possible, revealing previously unsuspected shock-heated gas in the intra-cluster medium (ICM) of clusters previously thought to be dynamically relaxed (Komatsu et al. 2001, Kitayama et al. 2004, Mason et al. 2010, Korngut et al. 2011, Plagge et al. 2012). These  $10''$  to  $20''$  SZE images are the current state of the art. A Band 1 receiver system on ALMA would surpass this benchmark, making detailed studies of the ICM using the SZE possible on larger samples and with greater sensitivity than has henceforth been possible.

ALMA Band 1 will be capable of addressing a wide range of basic questions about the observed structure and evolution of clusters, including: what is the structure of ICM shocks and the mechanism(s) responsible for converting gravitational potential energy into thermal energy in the intra-cluster medium (Markevitch et al. 2007, Sarazin et al. 1988)? What is the influence of Helium ion sedimentation within the cluster atmosphere (Ettori et al. 2006)? What is the nature of AGN-inflated "bubbles" seen in the cores of some clusters (Pfrommer et al. 2005), and what is the role of cosmic rays in the ICM? What is the nature of the underlying ICM turbulence (e.g., Kolmogorov versus Kraichnan)? A particularly rich area will be the detailed study of ICM shocks, which are common since infalling sub-clusters are typically moderately transsonic. Several galaxy cluster mergers have been observed recently with Chandra and XMM in X-rays with resolutions at the arcsecond level where substructures become visible (Markevitch, et al. 2000, 2002). The features of interest for these studies will typically fit within one or a few ALMA Band 1 fields-of-view and require longer integrations (several to  $\sim 10$  hours per pointing). Band 1 also has the sensitivity to detect the SZ effect for halos from individual galaxies (at least for massive ellipticals), as well as for groups (postulated signal strength of 20 microJy near 30 GHz).

Another important area where resolved SZE imaging will have an impact is the interpretation of SZE survey data. ACT (Dunkley et al. 2011), SPT (Williamson et al. 2011), and PLANCK (Planck Collaboration, 2011) have all conducted 1000+ square degree surveys to detect and catalog galaxy clusters via the SZE. These surveys provide unique and valuable information about cosmology but their interpretation depends upon assumptions about the relationship between the SZE signal and the total virial mass of the halo. It is known that both gravitational (cluster merger) and non-gravitational processes (AGN and supernova feedback, bulk flows, cosmic ray pressure) give rise to considerable scatter and potentially biases (e.g., Morandi et al. 2007) in this relationship. Cluster mergers have a particularly dramatic effect on the SZE, typically generating trans-sonic (Mach  $\sim 2-4$ ) shock fronts which can enhance the peak SZE in the cluster by an order of magnitude (Poole et al. 2007, Wik et al. 2008). These systematic astrophysical uncertainties are already the limiting factor in making cosmological inferences from the small published samples of a few dozen SZ-selected clusters (e.g., Sehgal et al. 2011). ALMA Band 1 is the only imminent observational capability which will be capable of efficiently observing the large southern hemisphere samples of SZE-selected clusters sufficiently rapidly to directly improve inferences from these surveys, which it will do by imaging (at  $5''-10''$  resolution) galaxy clusters discovered in

## < ALMA Band 1 Receiver Development Study >

Doc #: < 9145A, Rev **H1** >  
Date: < 2013-06-26 >  
Page: 11 of 57

the low-resolution ( $\sim 1'$ ) surveys, detecting shocks and mergers and identifying ICM substructure, and providing a direct, phenomenological handle on important survey systematics.

The coming decade will also see an explosion of optical and x-ray cluster data. The German/Russian X-ray satellite eRosita, due to launch in 2013, will carry out the first all-sky survey since ROSAT and is expected to catalog  $\sim 100,000$  clusters out to  $z=1.3$  (Cappelluti et al. 2011). The Dark Energy Survey (DES-- The Dark Energy Survey Collaboration, 2005) is a  $5,000 \text{ deg-squared}$ , mostly southern sky survey also expected to find  $\sim 100,000$  galaxy clusters. Targetted SZE observations with ALMA Band 1 will be invaluable to determine the properties of clusters at redshifts where x-ray spectroscopy and gravitational lensing begin to fail. These high- $z$  clusters, such as the ACT-discovered SZ cluster "El Gordo" at  $z=0.89$ , weighing in at  $M=(2.16\pm 0.32)\times 10^{15} \text{ Msun}$  (Menanteau et al. 2011), offer leverage on so-called "pink elephant" tests capable of constraining cosmological or gravity theories based on the existence of individual extreme objects provided their properties are accurately determined. It is worthy of note that in addition to the high-resolution capability, a Band 1 equipped ALMA Compact Array (ACA) will be comparable in capability to the OVRO/BIMA arrays which have been used in the current decade to measure the bulk SZE properties of large northern hemisphere cluster samples (Bonamente et al. 2008). Extending this capability the southern hemisphere over the next decade is important to realize the full potential of these rich cluster samples.

The high image fidelity and dynamic range of ALMA will be an advantage in these studies--particularly the deep, detailed astrophysical studies-- as will the ability to use longer baselines to accurately remove intrinsic and background (gravitationally lensed) discrete source populations. These populations are a signal of substantial interest from another point of view, but which will set a significant "confusion noise" floor to millimeter single-dish observations, especially considering the factor of 2-3 boost in source confusion in clusters due to gravitational lensing (Blain et al. 2002).

ALMA Band 1 will have a considerably higher sensitivity for these observations than the Jansky VLA, owing to an order of magnitude higher surface brightness sensitivity, or ALMA Band 3, owing to lower system temperatures and larger primary beam. We simulated Band 1 and Band 3 observations (50 12-m's and ACA) covering the virial region ( $D\sim 5'$ ) of a moderately massive SZE cluster with a merger shock (see [Figure 1](#)). We considered a hypothetical project aiming to detect a feature with a Compton  $y = 10^{-4}$  --- characteristic of strong shocks in major mergers--- over the virial radius of a cluster, with a characteristic feature size of  $5''\text{-}20''$ . The required flux density sensitivity is similar in both cases after allowing for resolution effects, about 8-9  $\mu\text{Jy RMS}$  (1  $\sigma$ ) in both instances. We find that a clear detection is achieved in only 1.5 hours of Band 1 observing, but nearly 40 hours are required at Band 3. The ACA Band 1 measurement of the bulk ICM signature (a 12h observation is needed for good SNR) is also shown, tapered to a  $45''$  (FWHM) beam. Yamada et al. (2012) find similar results in a detailed study of SZE imaging with ALMA and the ACA over a wide range of wavelengths,  $800 \text{ micron} < \text{wavelength} < 1 \text{ cm}$ .

Page: 12 of 57

### 3.0 Subsystems Studied

This report provides details for a proposed receiver architecture for ALMA Band 1 along with LNA, LO, and down-converter designs.

#### 3.1 Proposed Receiver Architecture

The optimum overall receiver architecture was also studied and is documented in this section. Note that the horn-lens, or horn with warm optics, were not included in the NRAO design study.

The block diagram of the overall architecture, shown in [Figure 2](#), minimizes components in the cold space for better maintainability. That is, cryogenic LNAs have sufficient gain that using room temperature mixers for frequency down-conversion should not result in any significant noise penalty. It is difficult to cover the desired bandwidth while preserving residual performance on the lower band edge using a single mixer with input filters to reject unwanted side-band, so the proposed design uses the SSB scheme. This arrangement reduces the number of penetrations of the vacuum vessel for this band (only two, compared to four if the mixers were to be located inside the cold cartridge). It also minimizes the heat load inside the cryostat.

A conventional YIG oscillator architecture is used that is similar to those already employed for other bands, thereby maintaining uniformity of interfaces.

It is desirable to minimize components in the cold space because experience from ALMA operations shows that it is much faster to get the receiver back “on the air” if the fault is outside of the cold space, since the cryostat does not have to be warmed up to extract/replace the offending cartridge. This approach also minimizes disturbing the optics during repair and that reduces the significant requalification effort required to remeasure optics performance after repair. To reduce the possibility of vacuum leaks, as well as lower the cumulative leak rate of the cartridge, the number of penetrations of the 300 K base plate should be minimized.

Concern about phase stability with mixers installed on the WCA resulted in a study of phase stability for Band-1 and the existing stability specifications should be comfortably met in part because phase drift is not a significant concern for this band. The specification stems from the requirement that change in phase delay should not be a significant contributor compared to the atmospheric contributions and was derived for the best atmospheric conditions (low pwv) when observing higher ALMA bands. It was directly applicable to Band-3 (and perhaps Band 4) which is a calibration band but that does not apply to Band-1 even though the same specifications have been tentatively copied. The use of RF mixers outside of the (temperature stabilized) cold space is therefore practical. Also, note that there are second down-conversion mixers (in the BE system) which operate at commensurate frequencies and have not caused any stability issues.

Mechanical layout drawings are shown in [Figure 3](#) for the overall cartridge, [Figure 4](#) as a top view of the cold stage, and [Figure 5](#) is a side view of the same cold stage components.

### 3.2 LNA

Three prototypes of 35 to 52 GHz amplifier were developed during the course of this study. The outside dimensions of all three versions are the same and a photograph of one of the versions is shown in [Figure 8](#). Note that input and output can be located on either side of the block. The HEMT devices used in all three versions are the same: first and second stage are employing 60 microns and 80 microns wide devices from NGST/JPL “cryo3” wafer #041, respectively, while the remaining gain stages are using 100 micron wide WMAP/HRL devices. Measured and modeled results of gain and noise temperature of the first prototype employing only 4 stages are shown in [Figure 9](#). The measured and modeled S-parameters for this amplifier are shown in [Figure 10](#). The gain of this amplifier is not large enough to sufficiently eliminate the noise contribution of room temperature down-converter. As a result, two versions of 5-stage amplifier were built and tested. The measured and modeled characteristics of these two versions are shown in [Figure 11](#), [Figure 12](#), [Figure 13](#) and [Figure 14](#). The differences between these two 5-stage versions mostly rest in slightly flatter noise temperature across 32-52 GHz frequency range of the amplifier QA001. This version is considered to be optimal from the point of view of the noise performance required for ALMA Band#1.

Comparison of noise temperature for the three prototype LNAs vs. specifications is shown in [Figure 15](#). The set up used to measure gain and noise temperature is shown in [Figure 16](#). No noise temperature corrections were made for the dewar window, horn and room temperature down-converter. The effective noise temperatures of LN2 and room loads shown in [Figure 16](#) were assumed to be 79 K and 297 K, respectively.

Previously measured and modeled results demonstrate that measured results can be reliably predicted in the CAD model. The repeatability of gain and noise characteristics of amplifiers of this type of design is demonstrated in [Figure 17](#) and [Figure 18](#) which show the performance of several J-VLA 38-50 GHz amplifiers, about a hundred of which were built.

The gain compression for the prototypes discussed in the preceding was not measured. However similar LNAs, using the same output stage, were evaluated and 1-dB gain compression point was found to be at about -4.2 dBm of output power for the amplifier when biased for low noise at a physical temperature of 20.7K. The dependence of output power at 38 GHz on the input power for that amplifier is shown in [Figure 19](#).

#### 3.2.1 LNA Proposed Specifications

The cryogenic LNAs shall connect to the output flanges of the cartridge’s orthogonal mode transducer (OMT) and amplify the signal according to the specifications given in [Table 4](#). Two LNAs are required for each cartridge to independently amplify the orthogonally-polarized signals available at the output of the OMT.

Table 4 : Low Noise Amplifier Specifications<sup>1</sup>

Ref #	Parameter	Specification
1	Frequency Range	35.0 – 50.0 GHz inclusive.
2	Noise Temperature	≤ 13 K over 80% of band ≤ 18 K over entire band
3	Gain (S <sub>21</sub> )	≥ 35 dB
4	Gain Flatness	In any 2 GHz bandwidth: ≤ 4 dB Peak to Peak, across entire RF band: ≤ 6 dB Peak to Peak
5	Input Return Loss (S <sub>11</sub> )	Better than 3 dB
6	Output Return Loss (S <sub>22</sub> )	Better than 4 dB

<sup>1</sup> All specifications assume physical temperature of LNA is in range 15K ≤ T ≤ 20K

Table 4 : Low Noise Amplifier Specifications<sup>1</sup>

Ref #	Parameter	Specification
7	Dynamic Range	Large signal compression $\leq 5\%$ for hot load temperature change from 77K to 373K
8	RF Input Flange	Square waveguide flange, WR-22, with holes for alignment pins (pin location TBD)
9	RF Output Flange	Square waveguide flange, WR-22, with holes for alignment pins (pin location TBD)
10	Power Dissipation	$\leq 29\text{mW}$
11	DC Supply	Bias from ALMA Bias card as specified in <a href="#">[RD 01]</a>
12	Power Connector	ITT Micro-D M83513/01-BN
13	Mass	(TBD)

### 3.3 OMT

A prototype Band 1 OMT was produced based on an existing Ku-Band (11 – 18 GHz) design, which was built for the GBT Pulsar wide band receiver and has the following characteristics:

Square waveguide	0.610" x 0.610"
Rectangular waveguide	0.610" x 0.305"
Stepped transition height	0.305" $\rightarrow$ 0.133"
E-plane combiner- steps	0.286" to 0.305"
Radius of bend:	1.5 $\lambda$
External dimensions	5.9" x 4.25" x 2.6"
Flange	UG-419
S <sub>11</sub>	$\geq 20$ dB over 47% bandwidth

Measured reflection coefficients and insertion loss for this OMT is shown in [Figure 20](#) and cross-polarization and isolation are shown in [Figure 21](#). Noise performance of the GBT using this OMT is shown in [Figure 22](#).

The Band 1 OMT has the following dimensions<sup>2</sup>:

Square waveguide	0.2112" x 0.2112"
Rectangular waveguide	0.2112" x 0.1056"
Stepped transition height	0.1056" $\rightarrow$ 0.0460"
E-plane combiner- steps;	0.0990" to 0.1056"
Radius of bend:	3.3 $\lambda$
External dimensions	4.2" x 3.2" x 1.5"
Flange	UG-383
S <sub>11</sub>	$\geq 20$ dB over 33-52 GHz (45% bandwidth)

[Figure 23](#) highlights the essential elements of this turnstile junction design. Machined parts are shown in [Figure 24](#) and two assembled units are shown in [Figure 25](#). Simulated performance is graphed in [Figure 26](#). Room temperature measurements of reflection coefficient, insertion loss, and polarization isolation are shown in [Figure 27](#) and [Figure 28](#). Consistency in manufacturing is shown in [Figure 29](#), where reflection coefficients from 3 different OMTs measure nearly the same, including the location of nulls.

<sup>2</sup> The tool radius and radius of the bend for the OMT was not scaled.

**< ALMA Band 1 Receiver Development  
Study >**

Doc #: < 9145A, Rev **H1** >

Date: < 2013-06-26 >

Page: 15 of 57

The OMT was gold plated to reduce room temperature insertion loss and the loss decreased from 0.9 dB to 0.35 dB worse-case at 35 GHz as shown in [Figure 30](#). The OMT will operate in the 15K stage of the cartridge, and [Figure 31](#) is used to predict that the insertion loss will decrease to 0.12 dB when cooled to 15K.

### 3.4 Down Converter

A prototype down-converter was designed and measured that uses quadrature phasing to provide image rejection and would be installed in the warm space of the WCA. [Figure 51](#) is the schematic of the proposed design and [Figure 54](#) is a photograph of the commercially-available, prototype components. An essential element of this approach is the RF hybrid, which is discussed in Section 2.4.1.

[Table 6](#) provides gain and noise calculations for the proposed receiver configuration, which meets the 80% bandwidth noise specifications. The contribution of the optics is not included in this table, which is estimated to add about 10 K to the receiver noise temperature.

Sufficient RF gain within the cold cartridge allows us to overcome the noise introduced by the room temperature mixers. A WR-22 to 1.85/2.4 mm coaxial transition using G3PO hermetically sealed connectors inside the dewar also serves as a vacuum feedthrough. This arrangement reduces the number of penetrations of the vacuum vessel for this band (only two, compared to four if the mixers were to be located inside the cold cartridge) and parts are commercially available.

#### 3.4.1 35-50 GHz Hybrid Design

The RF hybrid is an essential element of the down converter design shown above. The prototype 30-52 GHz hybrid designed by the NRAO as part of the Band 1 project uses a three-layer sandwich construction as shown in [Figure 35](#). Track metallization is on the two sides of the middle layer while the outer layer includes the ground planes. Plated-through holes define the RF channel and cutouts expose the tracks for attaching connectors.

[Figure 36](#) shows predicted s-parameters for the RF hybrid, while [Figure 37](#) through [Figure 39](#) are measured results for the delivered RF hybrid, and large discrepancies are found compared to predicted results. Subsequent VNA time domain measurements hinted that the substrate fabrication for the delivered hybrid was much thinner than specified. To confirm this, the dielectric thicknesses of the various layers were measured by looking edge-on under the measurement microscope, [Figure 40](#)., and two discrepancies were found:

1. The middle CuFlon layer is only 11.4  $\mu\text{m}$  (0.00045") thick compared to the specified thickness of 25.4  $\mu\text{m}$  (0.001"). This is either due to the pressure applied during the lamination process, or more likely, the vendor Polyfon used the next thinner substrate by mistake. The [CuFlon product data sheet](#) has both the 25.4  $\mu\text{m}$  (0.001") as well as 12.7  $\mu\text{m}$  (0.0005") on the list of standard thicknesses for the laminates.
2. Although probably not too significant, the compound (see grey bands in the pictures) used to glue and laminate the three layers together adds 33  $\mu\text{m}$  (0.0013") to each of the outer 127  $\mu\text{m}$  (0.005") CuFlon layers.

Using the measured thicknesses of the delivered RF hybrid, a CST simulation [Figure 41](#) shows fair agreement with measured results for the delivered hybrids, [Figure 37](#) through [Figure 39](#). Although the return loss of 10 dB seen in the measurements is not fully explained (perhaps there are errors in the widths of track metallization), the frequency structure of the measured reflection trace is similar to that seen in the simulation results.

Assuming the RF hybrid is remanufactured to specified thicknesses, reasonable image rejection is expected down to 25 GHz, and the option exists to use WR-19 waveguide cut-off section in the RF section inside the dewar to provide additional image rejection at the low end, if needed.

[Figure 42](#) shows the measured results for the *IF* hybrid, which is the same hybrid used successfully to obtain ALMA specified image rejection as part of the Band 6 mixer-preamp assembly. Theoretical image rejection as a function of overall phase and amplitude imbalance is shown in [Figure 43](#).

[Figure 44](#) shows the set-up and [Figure 45](#) is measured results for the prototype down-converter, although it is important to note that this measurement excludes the RF hybrid. Output power variation follows the RF amplifier slope. The design can incorporate an equalizer in the final IF amplifiers to meet overall 6 dB requirement. Recall that specifications are 6 dB gain slope over the full IF band and 4 dB over any 2 GHz segment.

### 3.4.2 High Pass Filter

A high pass filter was designed using WR-19 waveguide at cutoff to reject LNA noise at frequencies below 32 GHz which fall outside of the range of single-sideband down-converter. Measured performance is shown in [Figure 46](#).

### 3.4.3 Hermetic, Blind-mating Dewar Transitions

Blind mating transitions are required to route RF signals from the cold space to the room temperature sections for the proposed down-converter. A hermetic transition from WR-22 to a blind-mate V-connector was designed as shown in [Figure 47](#) and its performance is show in [Figure 48](#). Return loss is better than 20 dB from 35 to 50 GHz.

Another hermetic blind-mating connector assembly was designed that transitions from WR22 to G3PO-V so that the blind mate G3PO V connector configuration can be used in the warm space on the cartridge 300K plate. The assembly is shown in [Figure 49](#) and the G3PO blind-mating V connector interfaces through the hole in the block. Return loss is shown in [Figure 50](#).

## 3.5 LO

The Band 1 LO design is based on and is compatible with all other LOs used for the ALMA project. A block diagram of the LO is shown in [Figure 51](#). It is possible to cover the receiver frequency range of 33 – 52 GHz using an LO range of 29 – 40 GHz directly by using ultra-wideband, fundamental YTOs without resorting to frequency multiplication in the AMC. [Figure 52](#) shows higher harmonics lie outside of the Band-1 RF range and [Figure 53](#) graphs measured output power for a YTO.

It is not necessary to optimize LO power as a function of observing frequency – the “PA” block in the WCA could be replaced with a “down-converter” block, containing receiver chain mixers, RF post amplifiers and LO amplifiers as needed, conserving the basic WCA topology used for other ALMA bands.

Given the low phase noise requirement for ALMA, the proposed commercially available YTO is the only choice for the broadband, electronically tunable Voltage Controlled Oscillator (VCO). [Figure 54](#) shows a prototype LO housed in the standard Warm Cartridge Assembly (WCA) and consisting of four basic modules, the source oscillator (*i.e.* YTO), the Active Multiplier Chain (AMC), the Power Amplifier (PA), and Monitor and Control Phase Lock Loop assembly. [Figure 55](#) is a photograph of a MCDPLL module with the cover off. Two SMA connectors are mounted on left side for FLOOG and AMC IF signals.

[Figure 56](#) shows the block diagram of the the experimental setup for phase noise (and drift) measurements which are recorded in [Figure 57](#). Integrated phase jitter (10 Hz to 10 MHz) measures ~ 20 fs and the phase drift is ~8.1 fs over 300 s which strongly suggests the proposed LO will meet phase drift specifications of 12 fs and phase noise specifications of 38 fs.

Page: 18 of 57

### 3.5.1 LO Proposed Specifications

The Local Oscillator (LO) generates a tunable CW signal that is input the first mixer and is phase locked to reference signals provided by the photonic mixer and the First LO offset generator (details shown in the ALMA receiver block diagram [\[RD 07\]](#) and is located in the warm space of the front end. The LO shall meet specifications given in [Table 5](#).

Table 5 : Local Oscillator Specifications		
Ref #	Parameter	Specification
1	Frequency Range	29.0 – 40.0 GHz inclusive.
2	Power	Output of each channel shall be $\leq +11$ dBm.
3	Excess Sideband Noise	Sideband noise refers to the noise accompanying the LO at frequency offsets within the IF band of the mixer in the normal operating RF frequency range. Since the receiver noise for Band 1 is determined by cryogenic low noise amplifiers (rather than a mixer front end) the receiver should be insensitive to LO sideband noise. Consequently, there is no formal constraint placed on LO sideband noise for this band.
4	Phase Noise	The short term phase stability ( $T < 1$ s) shall be less than 38 fs integrated from 1 Hz to 10 MHz for any frequency setting. Note that this only specifies the front-end LO electronics. Contribution from the LO reference shall be in addition to this.
5	Phase Drift <sup>3</sup>	The long-term phase stability ( $20$ s $\leq T \leq 300$ s) shall be less than 12.5 fs for any frequency setting. Note that this only specifies the front-end LO electronics. Contribution from the LO reference shall be in addition to this.
6	Spurious and Harmonics	Spurious Signals (coherent or incoherent) on the outputs of the LO drivers in the WCAs shall be $< -40$ dBc over the range of offset frequencies from the carrier from 500 Hz to 500 kHz and $< -50$ dBc from 500 kHz to 12 GHz. The components harmonically related to the YTO frequency shall not exceed -20 dBc.
7	Amplitude Stability	The Allan variance, $\sigma^2(2, T, 0.9^*T)$ , of the Band 1 first local oscillator output power shall be less than $9.0 \times 10^{-8}$ for $0.05$ s $\leq T \leq 100$ s and less than $1.0 \times 10^{-6}$ for $T = 300$ s.
8	LO Leakage / EMC	Shall comply with <a href="#">[RD 02]</a>
9	VSWR / Return Loss at the LO input port of the “cold” cartridge / mixer	Shall be better than 10 dB.

### 4.0 Costing Provided

Costing was provided to the Band 1 Down-Selection Review Panel in the document entitled “Costing for NRAO Band 1 Components” via e-mail dated Thu 2013-01-10 20:07. Costs were partitioned to show costs for production only as well as those costs for reviews and project management. The costing is considered proprietary to the NRAO and is not included in this final report.

Production schedules were provided during the Down-Selection Meeting, but are being updated as part of NRAO’s proposal and will be included in the proposal document.

### 5.0 Proposed Band 1 Cartridge Test Plan

[Table 7](#) provides a test plan for the components discussed in this document.

<sup>3</sup> The long term phase stability (delay drift) requirement refers to the 2-point standard deviation with a fixed averaging time,  $\tau$ , of 10 seconds and intervals,  $T$ , between 20 and 300 seconds.

**Figure 1: Simulated 1.5 hour ALMA Band 1 (left) and Band 3 (right) observations**

The observations are of a galaxy cluster covering  $5' \times 5'$ . The shock is represented as a Gaussian component  $5'' \times 25''$  in extent with a peak SZE of  $y=10^{-4}$ , considerably weaker than the amplitude observed in RXJ1347-1145 by Mason et al. (2010). The Band 3 data were tapered to the innate resolution of the Band 1 map,  $\sim 10''$  (FWHM). ACA baselines were not included in this simulation but the overplotted contours show the ACA Band 1 image (using a  $45''$  taper) of the bulk ICM in this system in a simulated 12h integration after subtraction of the shock signal. The bulk ICM is modeled as an elliptical isothermal beta model with  $R_{core} = (150, 250)$  kpc,  $\beta = 0.7$ , and  $y_o = 3 \times 10^{-5}$  at  $z=0.7$ , characteristic of disturbed, merging systems.

 Page: 56 of 57

5.3 <u>Feedhorn</u>		
Parameter to Measure	Measurement Conditions	Measurement Procedures/Notes
<b>5.3.1 <u>Common requirements</u></b>  (Specifications in this row apply to all subsections below)	Frequency Range: 33 – 52 GHz Maximum measurement step size: 5 frequencies across the band  Physical temperature during measurement: Room temp	Frequency range extends beyond specified RF band to check for gain peaks/dips etc. just outside specified bandwidth.  Ideally, the feedhorn will be measured at a physical temperature near the LN <sub>2</sub> boiling point, because there's little change in mechanical dimensions between 80 K and the operating point at 15 K. However, this is just a guideline. A comparison between measured performance and that calculated for the optics chain is suggested.
<b>5.3.2 <u>Match</u></b>	Measured for each polarization orientation	Return loss graphs in units of dB. Measured for both polarizations to ensure circularity of horn.
<b>5.3.3 <u>Cross-polarization Isolation</u></b>	Measured for both polarizations.	In theory, 45° cuts are sufficient to capture the peaks of the cross polarization lobes, but in practice, this is not always the case - particularly if the patterns have significant anomalies. Two-dimensional scans are ideal, and will capture peak cross-pol levels regardless of the cross-polarization pattern shape, but such a scanner cannot be deemed mandatory because its construction expense seems outside the scope of the down-selection process. Cross-pol measurements over more than 45° cuts are probably sufficient.
<b>5.3.4 <u>Beam Patterns</u></b>	Measured in E- and H- planes at least out to 2 <sup>nd</sup> or 3 <sup>rd</sup> sidelobes	
<b>5.3.5 <u>Phase Center</u></b>	Measured at 33, 35, 42.5, 50, and 52 GHz

5.4 Mixer (Down Converter)									
Parameter to Measure	Measurement Conditions			Measurement Procedures/Notes					
<b>5.4.1</b> <b><u>Common requirements</u></b>  (Specifications in this row apply to all subsections below)	LO Steps: 29 GHz 31 GHz 39 GHz 40 GHz	IF Range: 4 – 12 GHz 4 – 12 GHz 4 – 12 GHz 4 – 12 GHz	Resulting RF range: 33 – 41 GHz (optional) 35 – 43 GHz 43 – 51 GHz 44 – 52 GHz (optional)	Frequency range extends beyond specified RF/IF band to check for gain peaks/dips etc. just outside specified bandwidths.					
<b>5.4.2</b> <b><u>Image Rejection</u></b>				Step synthesizer at RF and measure IF power in both USB and LSB IF ports.					
<b>5.4.3</b> <b><u>Conversion Gain</u></b>	Includes IF amplifiers following mixer			Step synthesizer at RF and measure power for both USB and LSB ports.					
<b>5.4.4</b> <b><u>Gain Slope</u></b>	Includes IF amplifiers following mixer			<b>Full Band:</b> Calculated as $P_{max} - P_{min}$ in for any measured point in the IF from 4 to 8 GHz <b>2-GHz Band:</b> Calculated as $P_{max} - P_{min}$ in a 2-GHz wide window that slides across the IF from 4 to 12 GHz					
<b>5.4.5</b> <b><u>LO Power Required</u></b>				Found from the minimum LO power where mixer meets specifications					
<b>5.4.6</b> <b><u>Noise Figure</u></b>				Measured using noise source. At each LO frequency, step across IF range according to step sizes provided in Section <a href="#">5.4.1</a>					
<b>5.4.7</b> <b><u>Port Match</u></b>	Measured for the following ports: <ul style="list-style-type: none"> <li>• RF (input)</li> <li>• USB IF (output)</li> <li>• LSB IF 1 (output) (if used)</li> </ul>			Return loss graphs in units of dB					
<b>5.4.8</b> <b><u>Port-Port Isolation</u></b>	Measured for the following paths: <table border="0" style="width: 100%;"> <tr> <td style="width: 33%;">• RF to IF 0</td> <td style="width: 33%;">• LO to IF 0</td> <td rowspan="2" style="width: 33%;">• LO to RF</td> </tr> <tr> <td>• RF to IF 1</td> <td>• LO to IF 1</td> </tr> </table>			• RF to IF 0	• LO to IF 0	• LO to RF	• RF to IF 1	• LO to IF 1	(some designs may use only one IF output)
• RF to IF 0	• LO to IF 0	• LO to RF							
• RF to IF 1	• LO to IF 1								
<b>5.4.9</b> <b><u>Dynamic Range</u></b>				1. For each RF specified in Section <a href="#">5.4.1</a> , using LO input signal set for maximum specified power, increase RF power until IF output compresses by 1 dB. 2. For each LO frequency specified in Section <a href="#">5.4.1</a> , using RF input signal set for maximum specified power, increase LO power until IF output compresses by 1 dB.					
<b>5.4.10</b> <b><u>Harmonics</u></b>				Inject RF signal at maximum specified power, using maximum specified LO power, and record power level of spurious signals as RF and LO frequency changes.
