# First Hydrostatic Cores?

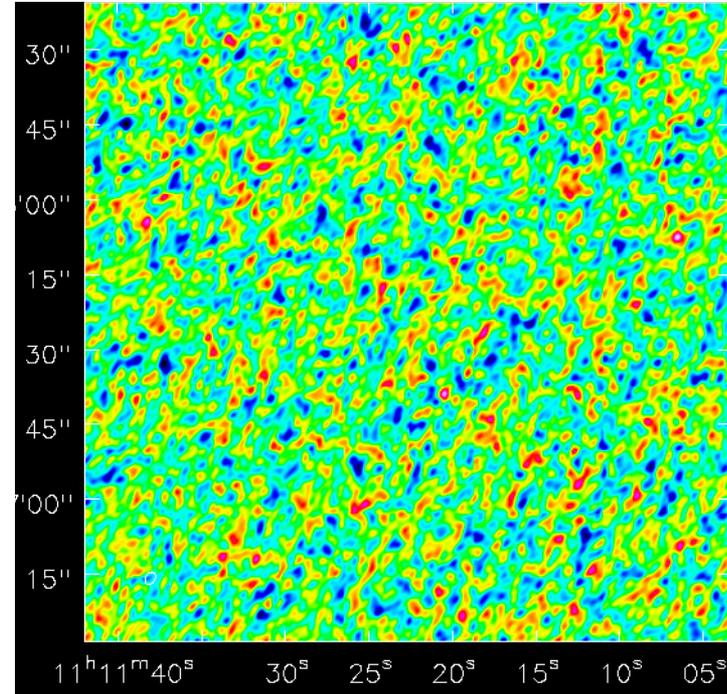

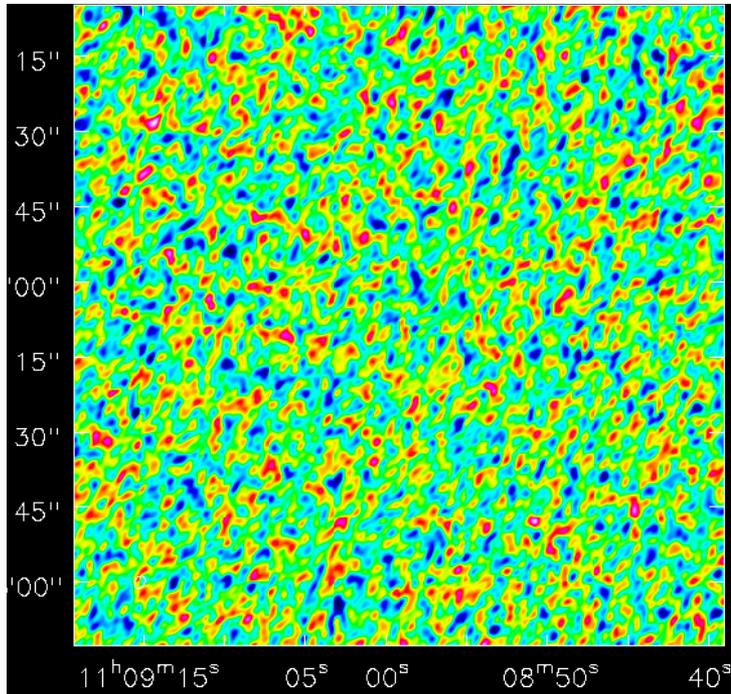

## In search of early phases of star formation

- An isothermal sphere approximates a pre-stellar core
  - Cf. Schnee cores—invisible to interferometry
- The first stage of star formation is thought to be the first collapse of that core to the FHSC ( $t \sim 500\text{-}1000$  years)
  - Only slow outflows at this stage
  - $n_{\text{central}} \sim 10^{10} \text{ cm}^{-3}$
- That is followed by the 2<sup>nd</sup> collapse, accompanied by  $\text{H}_2$  dissociation (few days) ( $T$  reaches  $\sim 2000\text{K}$ )
- As rotation couples with the collapse and embedded magnetic field, jetlike outflows arise and the star is on its way to Class 0
- This is an intrinsically low-contrast stage, invisible or difficult to image with interferometers.

# Starless Cores: Weak or No mm Continuum

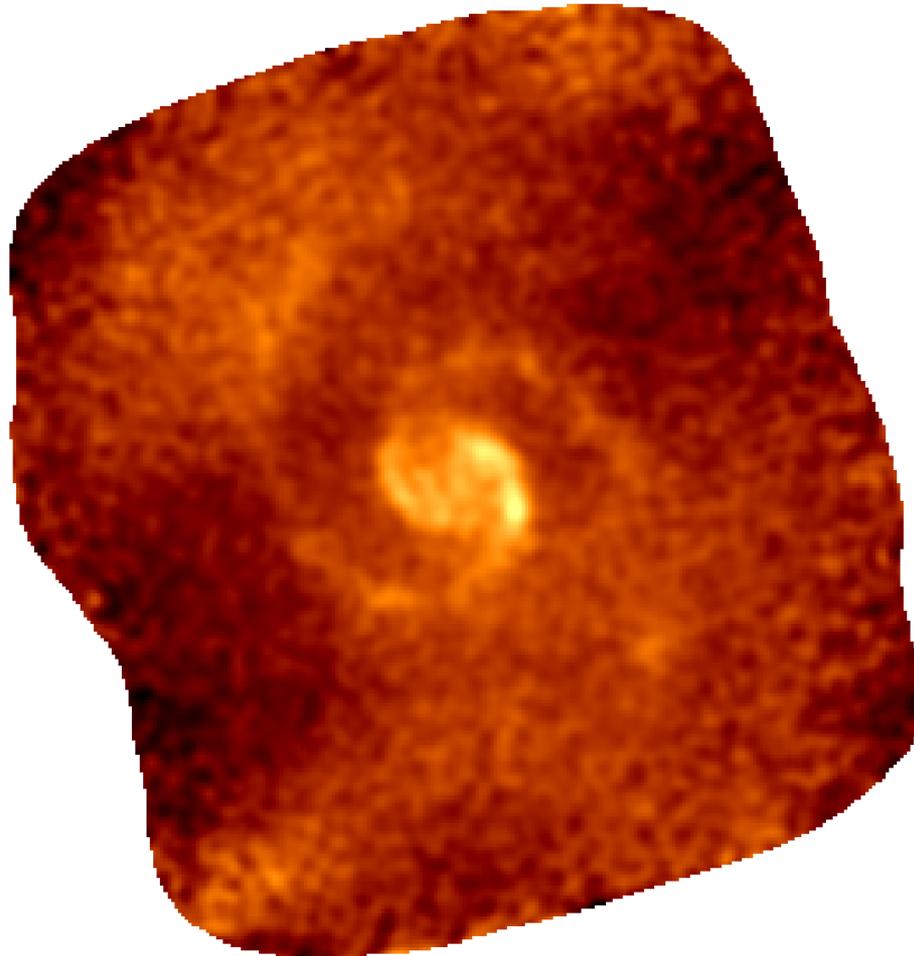

## Every Starless Core (ALMA) (Schnee et al. in prep.)

- For Starless cores, GBT has huge advantages over ALMA
  - SMA, CARMA, ALMA saw nothing (Schnee et al 2010, 2012, in prep)
- ALMA Total Power continuum modes are not on the radar screen
  - Continuum TP imaging using nutators
  - Continuum TP polarization
- An interferometer can, however, find low mass stars hidden within apparently starless cores

# Example: large scale TP is hard...

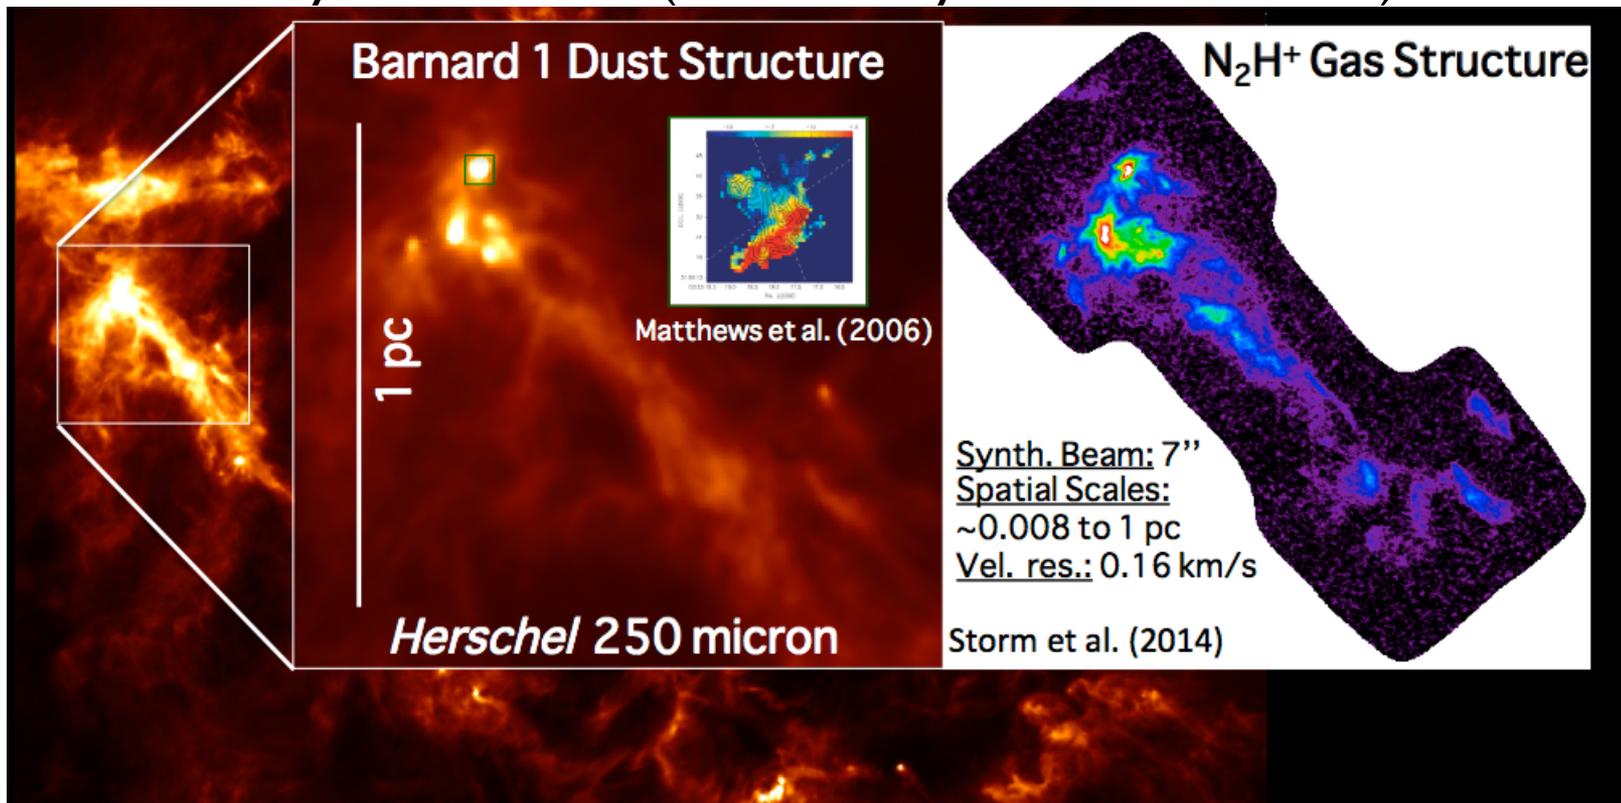

CSO Image of M51 dust with SHARCII bolometer array, no nutator

Problem: Large scale low-level baseline

ALMA TP array has nutators, not yet commissioned

# Early Stages of Star Formation

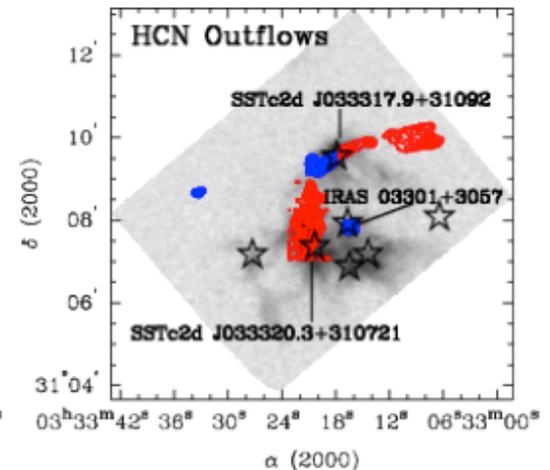

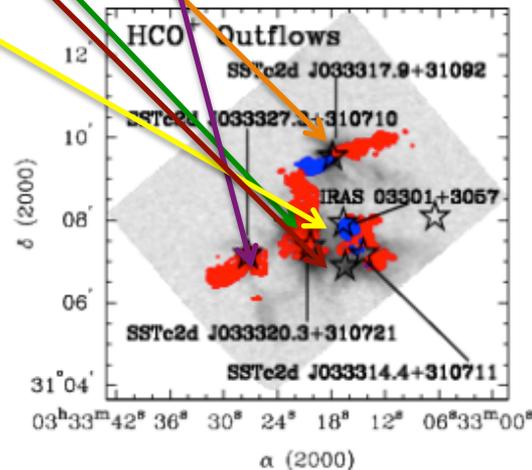

- To detail the physical parameters describing star formation we focus on star formation in the part of the Per BI core
  - Several cores are present, perhaps nearly coeval, in the nearby core
    - Distance = 230 pc, 1"=230 AU
  - Cores lie in a roughly filamentary region, large column densities
  - Relatively well-studied (see CLASSy Storm et al 2014)

# YSOs in BI

7 Spitzer Class 0/I YSOs, 4  $N_{\text{H}_2} > 10^{23} \text{cm}^{-2}$  dense cores

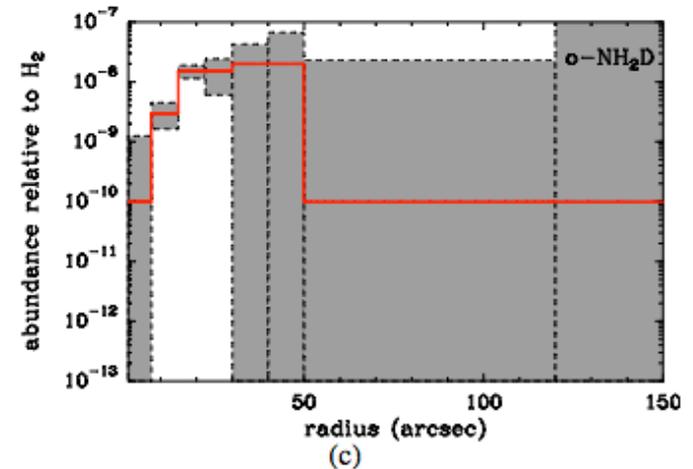

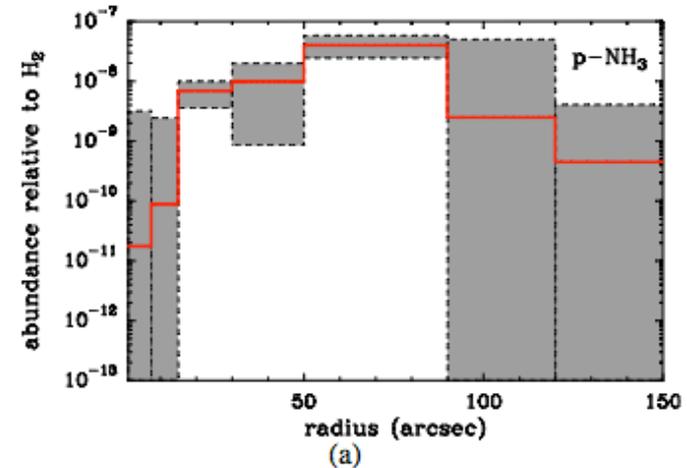

- B1c: A well developed core containing a star and outflow
- B1b:
  - Core contains at least two objects,
    - One is a star with outflow (B1bS);
    - Second also contains an object with an outflow (B1bN)
  - Third object, Per-emb 30, status has a red lobed outflow
- Also B1a and B1d

# Focus: Densest, Least Evolved Cores B1b S and N

- High column density
- High space density
- Large columns of deuterated species (Roueff et al, Marcelino et al, Gerin et al)
- Densest parts show depletion (Daniel et al) in many molecules, notably  $\text{NH}_3$  and  $\text{NH}_2\text{D}$ 
  - Marked in inner  $\sim 10''$  (2300AU)

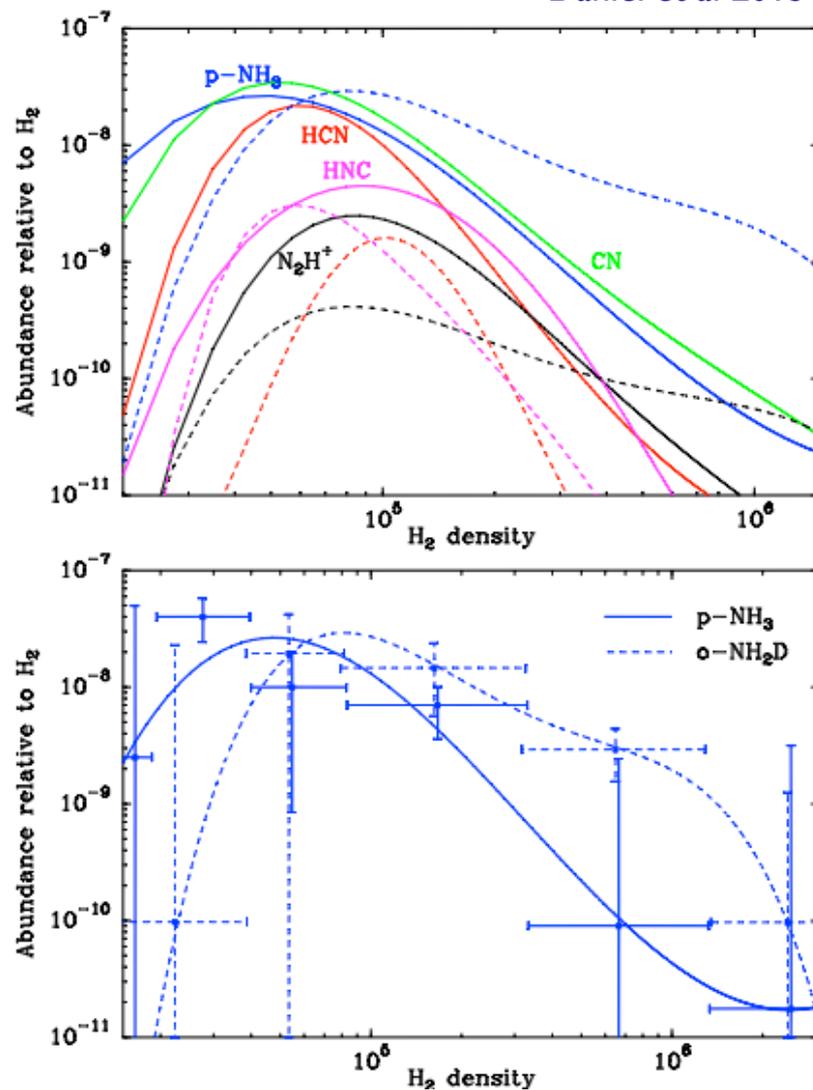

Daniel et al 2013

# Densest Core Material Strongly Depleted

- Suggests that probing physical conditions deep within the core hard
  - Very sensitive spectroscopy needed (large  $A_{\text{eff}}$ )
  - High resolution needed to ferret out signal from densest core (here  $\leq 10''$ )
  - A problem for large telescopes (GBT, VLA, ALMA, NOEMA)
  - Even then,  $\text{NH}_3$  is too depleted
- For now: what is the molecular content of the deep core?

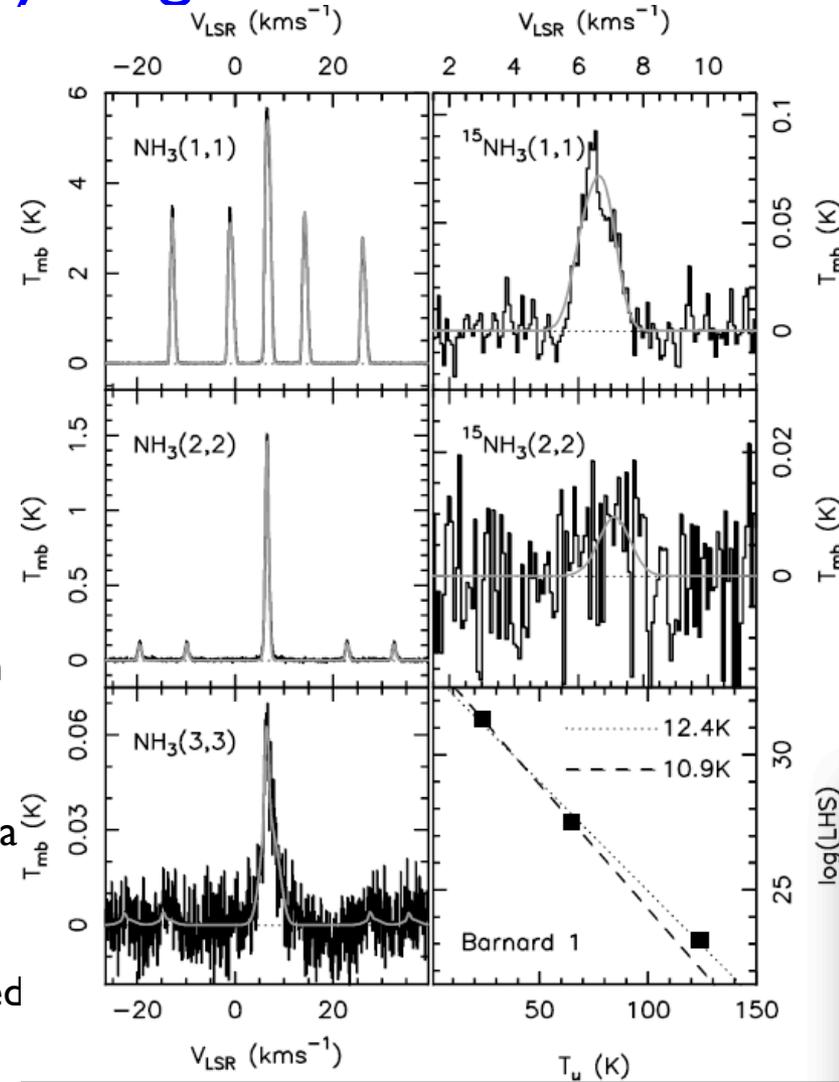

Daniel et al 2013

# Previous Observations: Frequency-targeted and Wideband

## Narrowband Deep Observations

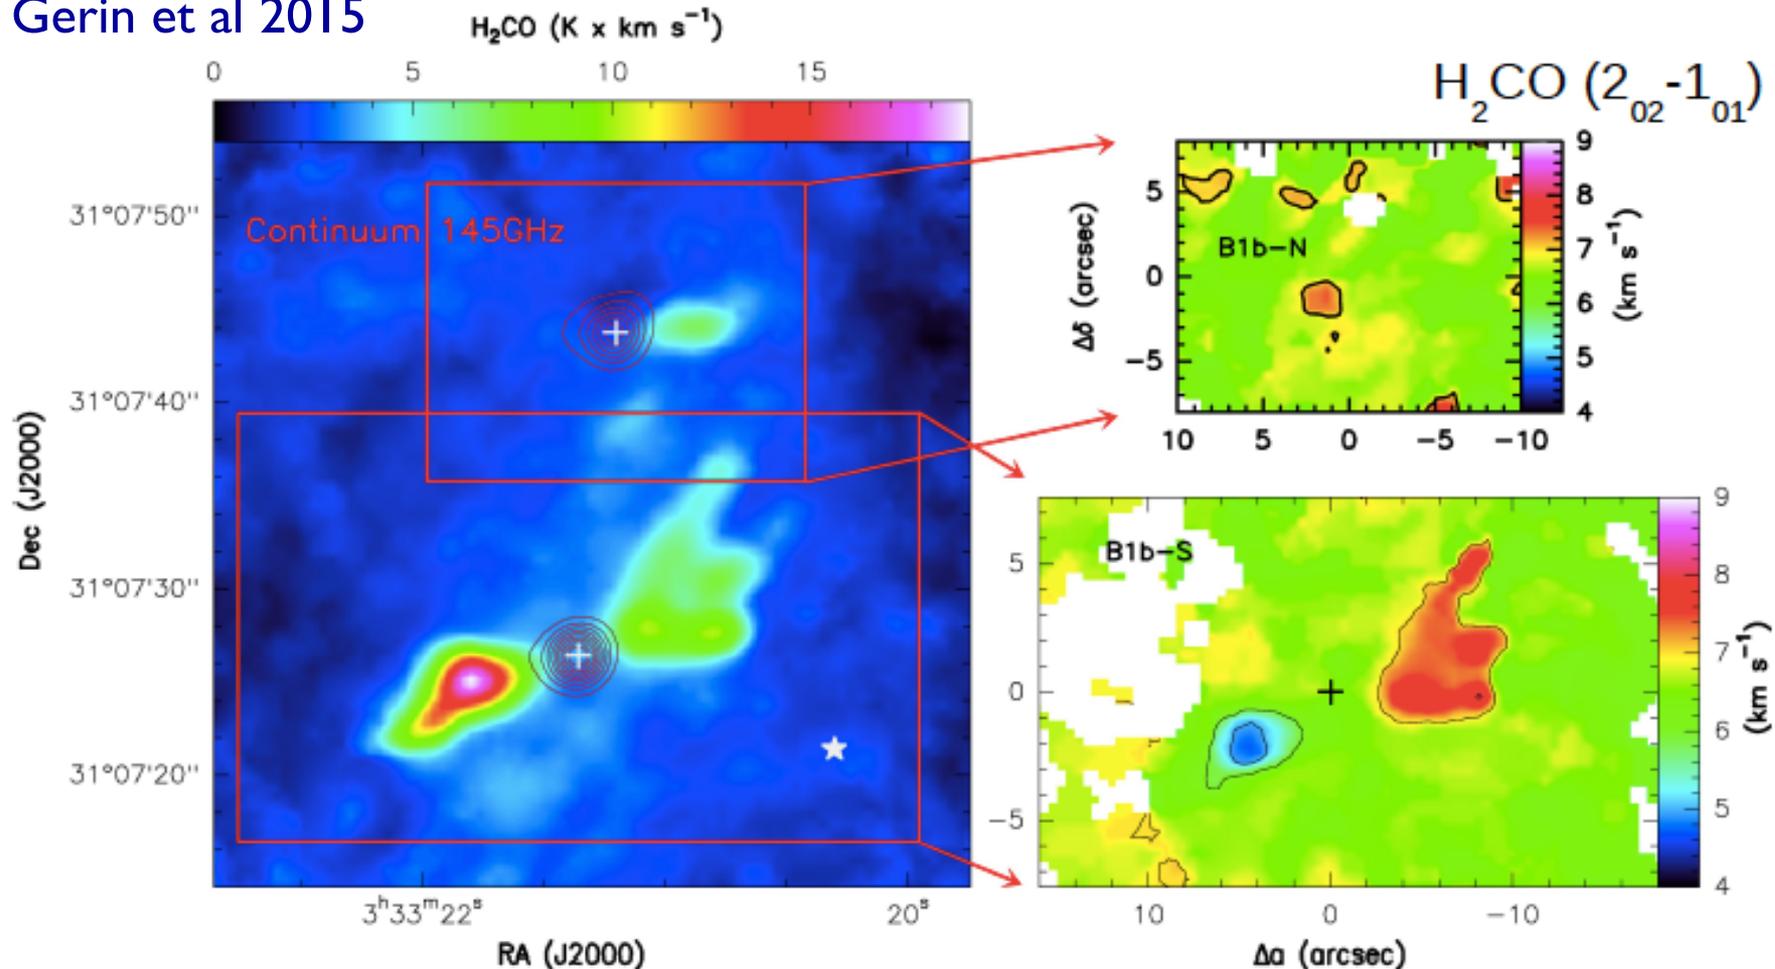

- Seeking weak lines of indicative species<sup>15</sup>N proposed to fractionate in very cold regions where D also becomes highly fractionated
  - Large column densities of singly and multiply deuterated species : ND<sub>3</sub>, <sup>15</sup>NH<sub>2</sub>D, D<sub>2</sub>S, D<sub>2</sub>CS, ... (Roueff et al., Marcelino et al '12., Gerin et al. '15 )
- Need ~3 hr to detect <sup>15</sup>NH<sub>3</sub> (1,1) lines observed w/GBT, broad backend
  - NH<sub>3</sub> (1,1) and (2,2) lines are narrow (~0.8 km s<sup>-1</sup>), but the (3,3) line has broad (~3.5 km s<sup>-1</sup>) pedestal—outflow? (e.g. <sup>15</sup>NH<sub>3</sub>: Lis et al. '10)
  - From the rotation diagram analysis we derive a low temperature, T<sub>rot</sub>=12.4 K, and N(NH<sub>3</sub>)=(2.1±0.3) × 10<sup>15</sup> cm<sup>-2</sup>
  - The <sup>14</sup>NH<sub>3</sub>/<sup>15</sup>NH<sub>3</sub> ratio is **304±49**, as compared to 470 (+170,-100) in NH<sub>2</sub>D
- A buried lurking higher excitation source
  - Detection of organic species CH<sub>3</sub>O, HCOOH, CH<sub>3</sub>SH, HCCCHO, CH<sub>3</sub>CHO, ... (Cernicharo et al. 2012)

Warm component: what and where is it and how does one characterize it?

# PdBI Observations

Gerin et al 2015

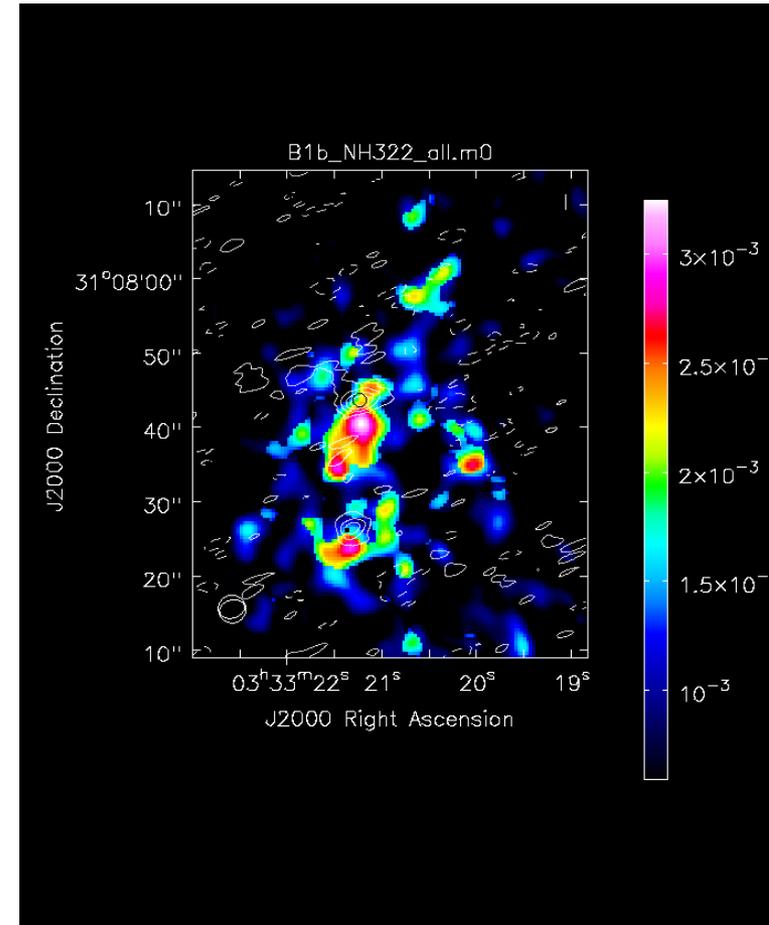

7-field mosaic in C+D configurations at 145GHz + IRAM-30m short spacings  
 Beam : 2.2 x 2.3" (500 AU) PA = 108°

H<sub>2</sub>CO (2<sub>02</sub>-1<sub>01</sub>) ; CH<sub>3</sub>OH (3<sub>K</sub>-2<sub>K</sub>) ; c-C<sub>3</sub>H<sub>2</sub> (3<sub>12</sub>-2<sub>21</sub>) ; DCO<sup>+</sup>(2-1) ; DCN (2-1)  
 ; Continuum

# VLA Observations of B1b (Marcelino et al in prep)

## Two protostars for the price of one!

- B1b-S: A well-developed protostar
- B1b-N: A First Hydrostatic Core??
- Observed:
  - $\text{NH}_3$  (1,1), (2,2), (2,1), (3,3) and (4,4),
  - $^{15}\text{NH}_3$  (1,1), (2,2) and (3,3),
  - $\text{HC}_5\text{N}$  J=9-8
  - $\text{HCNO}$  J=1-0
  - Continuum
- Results
  - Detected continuum
  - $\text{NH}_3$  (1,1) and (2,2): does not define core
  - Consistent with depletion at high n
  - Need zero-spacing data from GBT (available in archive)

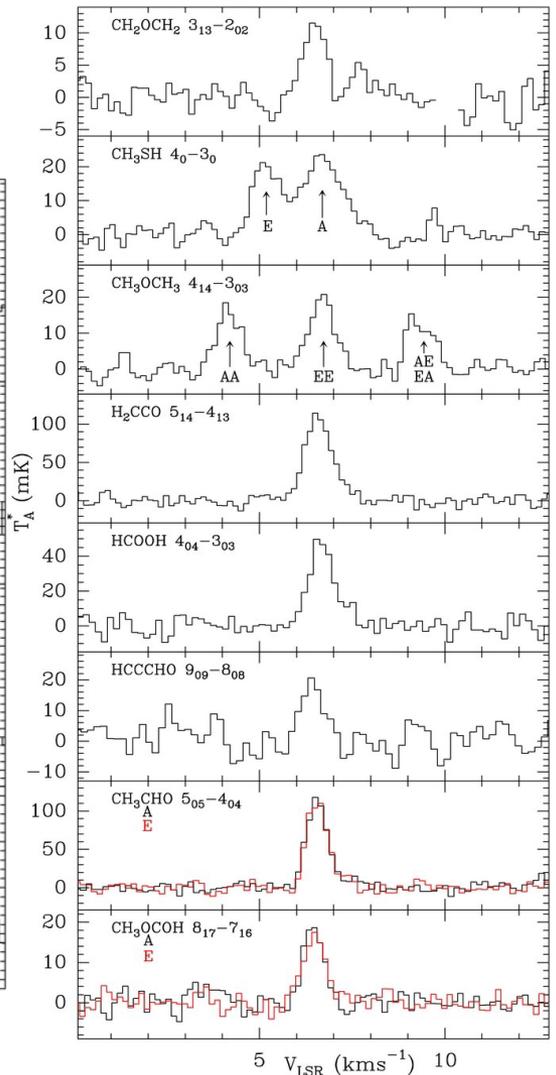

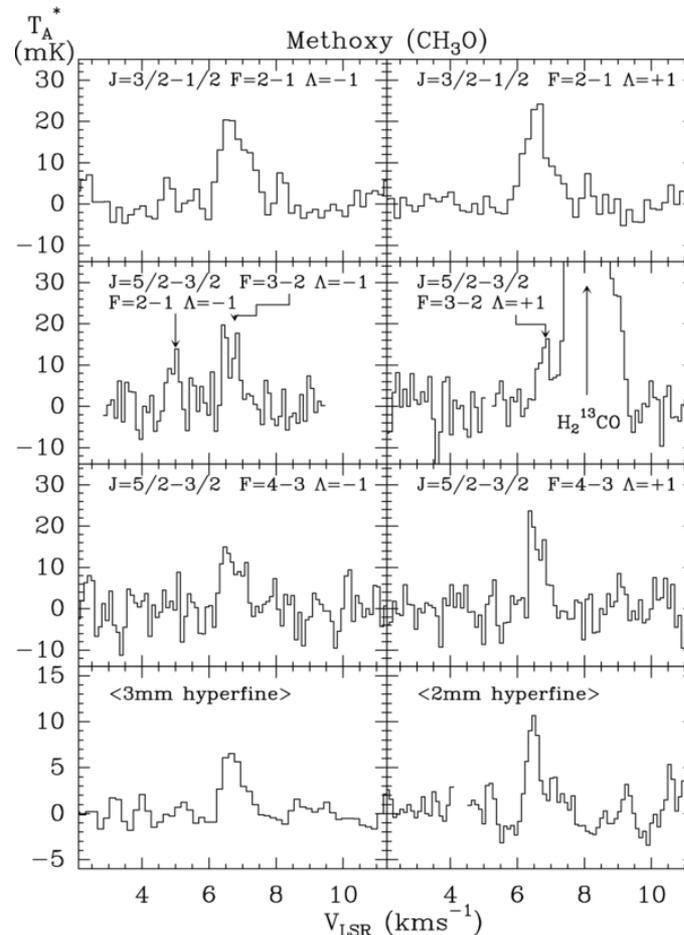

# Wideband spectral surveys of B1b

Starting with Cernicharo et al (2012) using venerable IRAM 30m

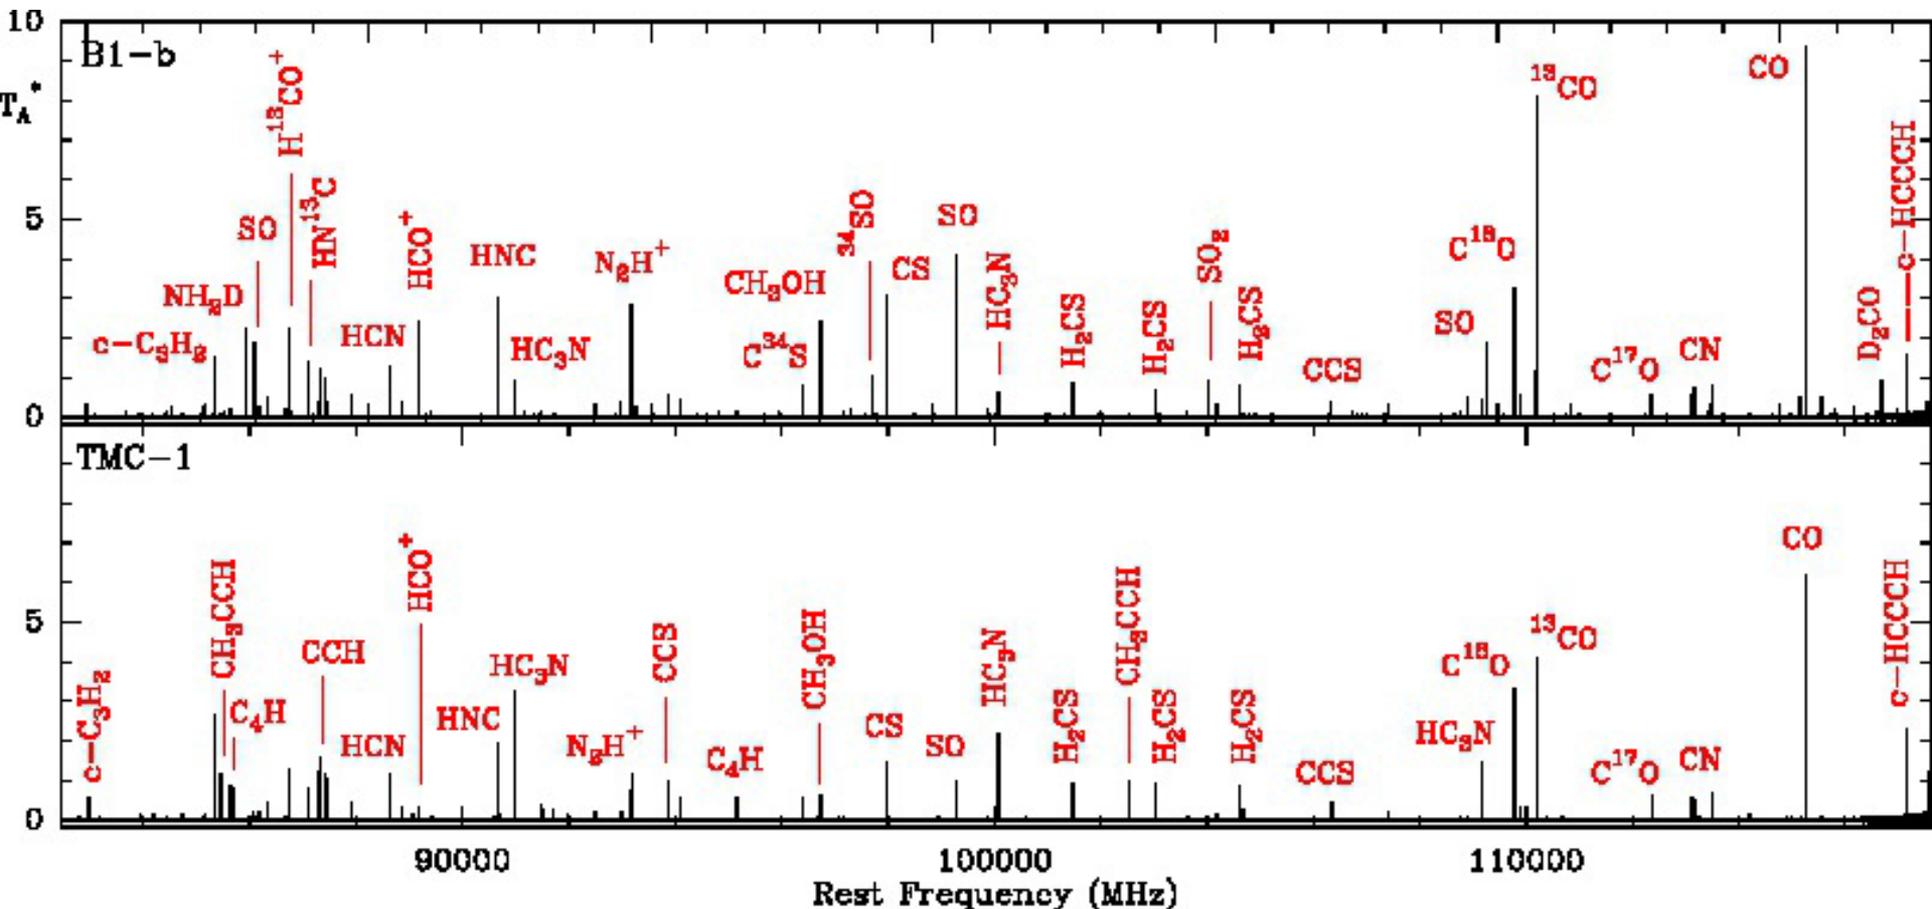

- EMIR receivers (83-117GHz, 2x4 GHzBW, DSB)
- 24 FFT spectrometers provide 50kHz resolution over 7.2 GHz
- Rms~4-6mK in 2 hrs per setting, or 15 hrs per source
- Beam 21-30" does not resolve sources

Discovery of Methoxy, rich spectrum

# IRAM scan

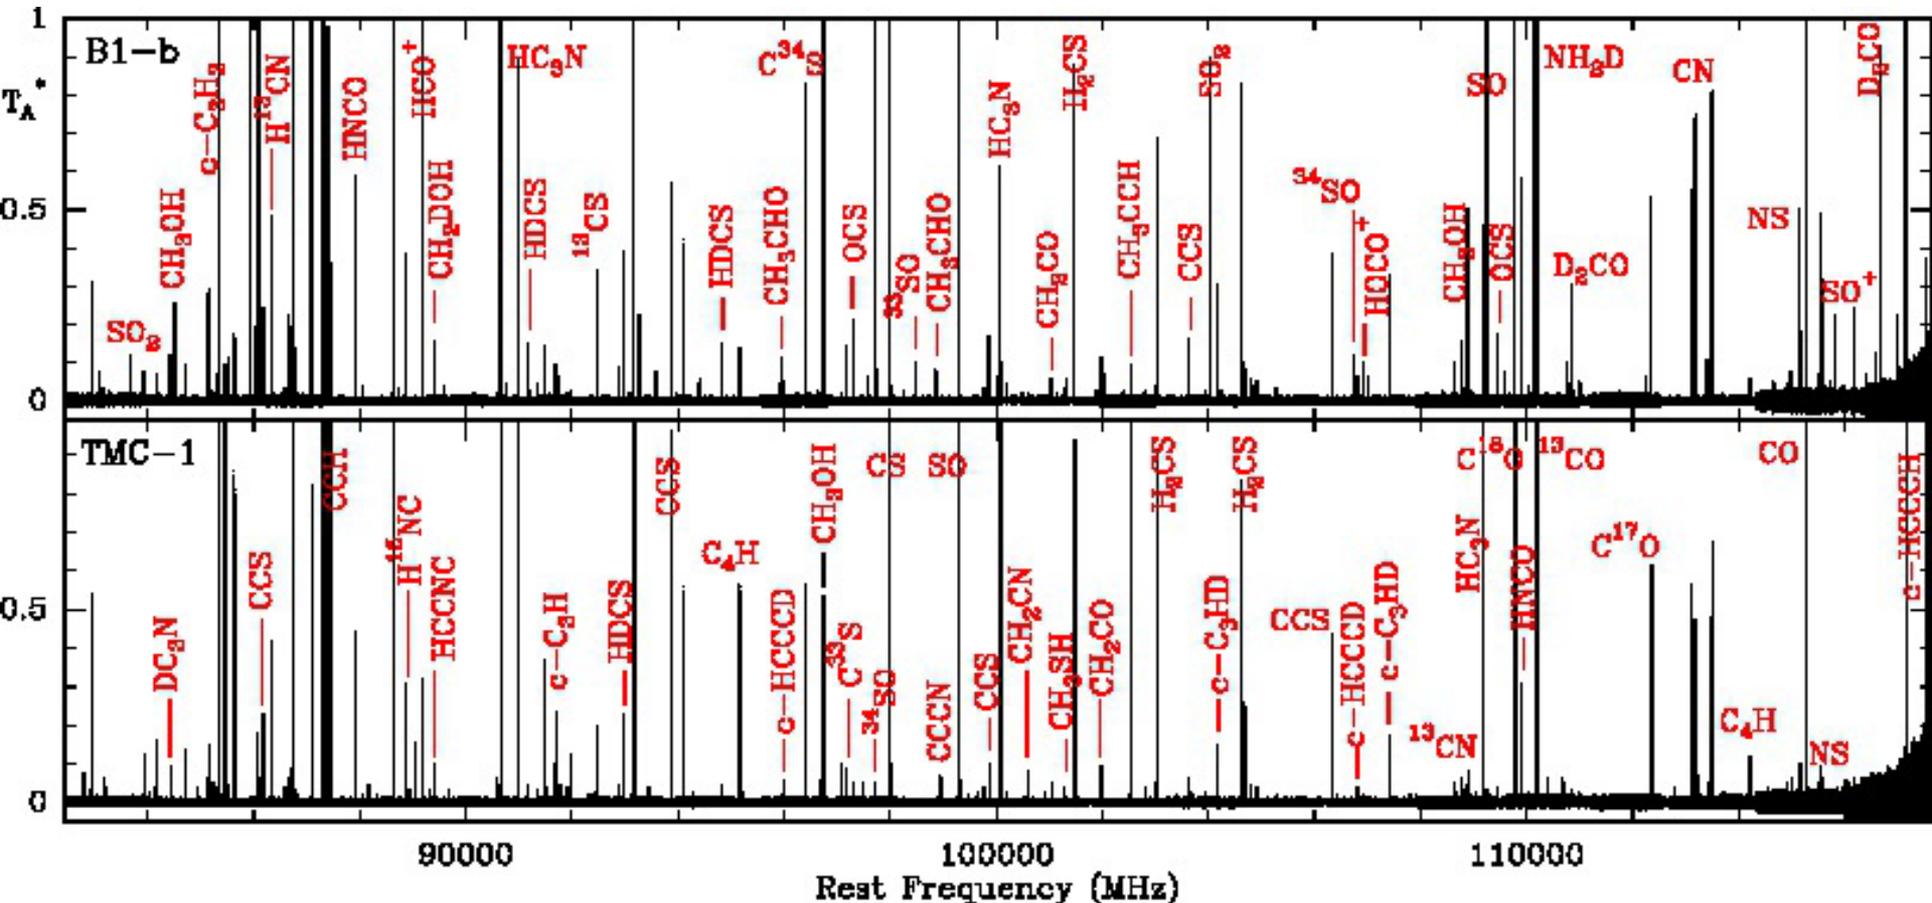

Marcelino et al (in preparation)

- Note the striking differences—owing to the protostar?
- 325 lines | 10 species.

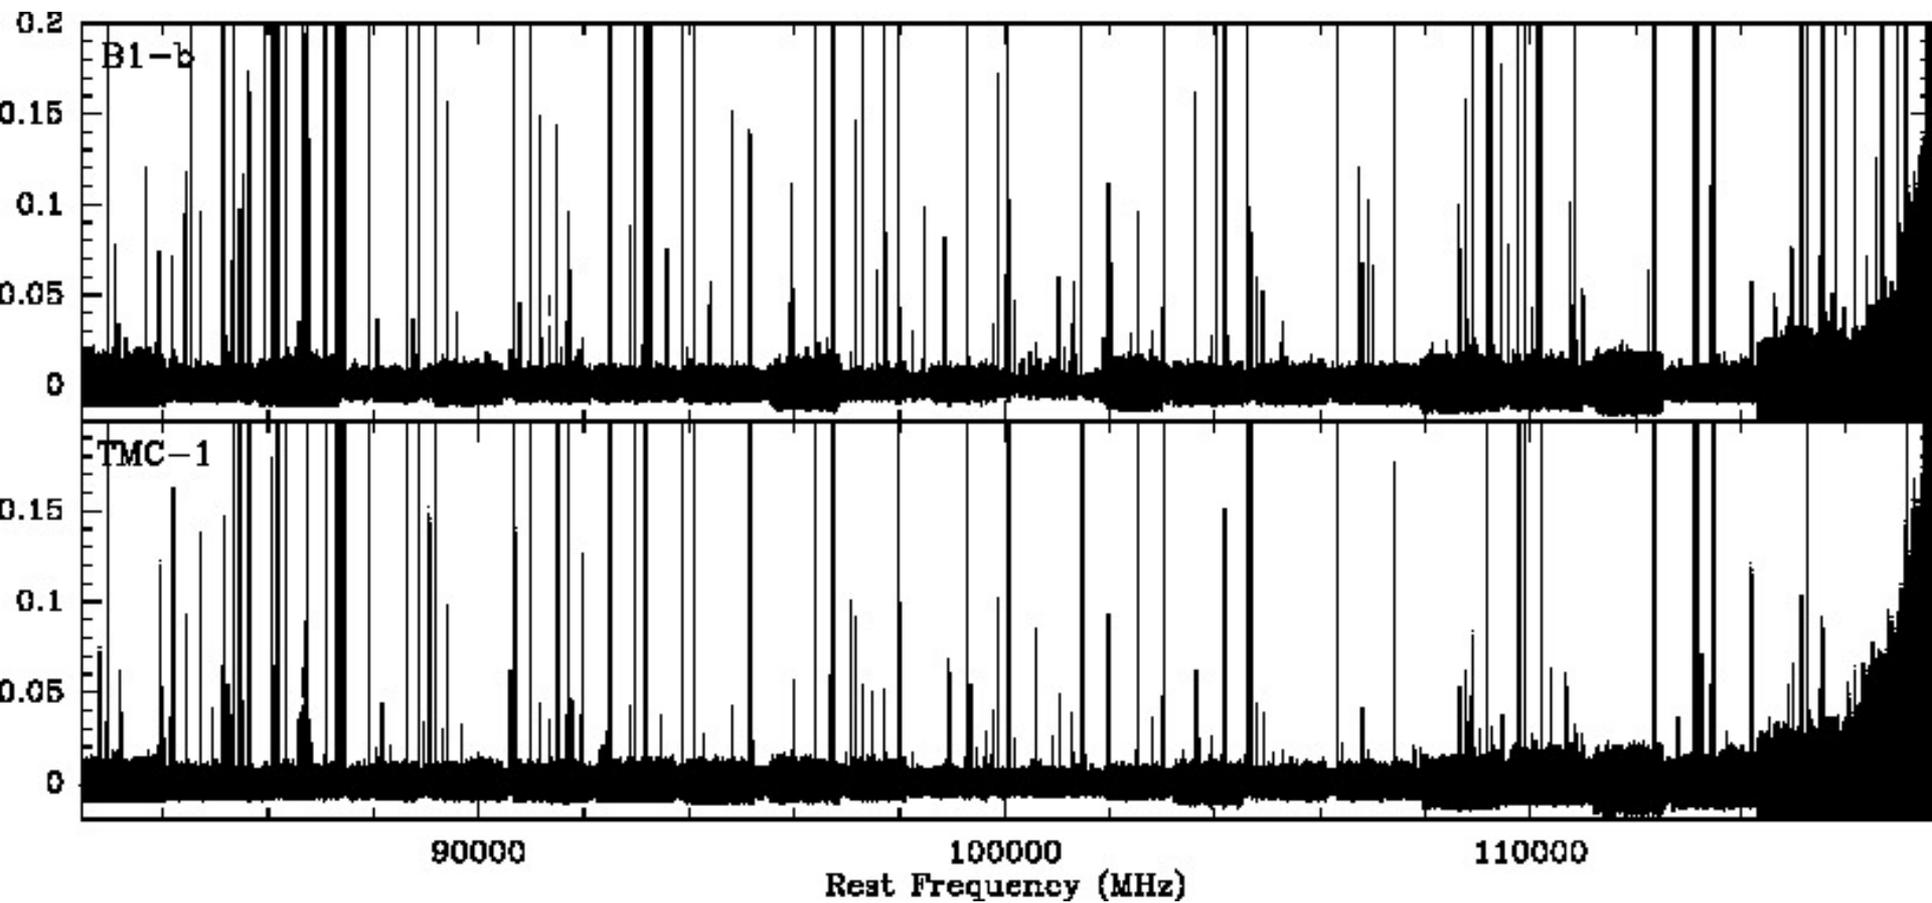

# Same scan higher sensitivity

Marcelino et al (in preparation)

# Even higher sensitivity

Marcelino et al (in prep)

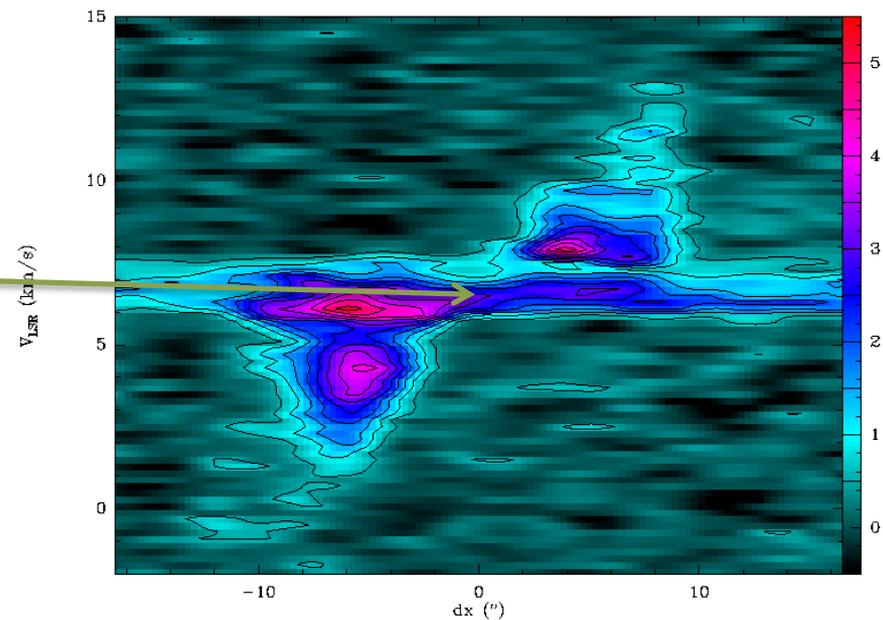

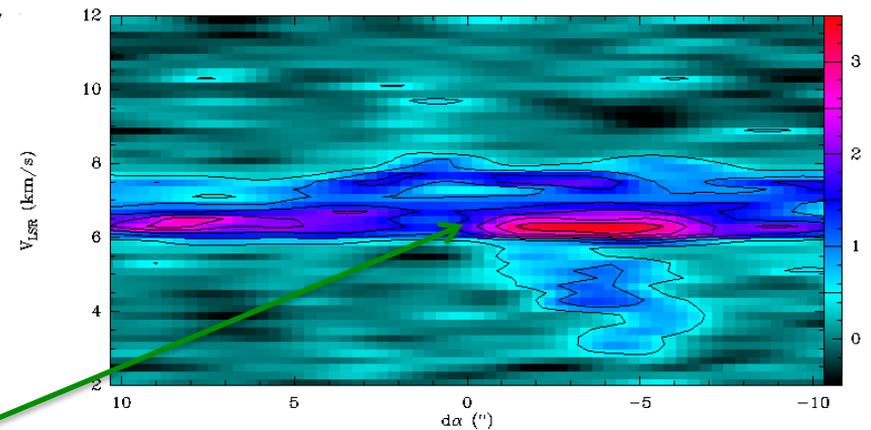

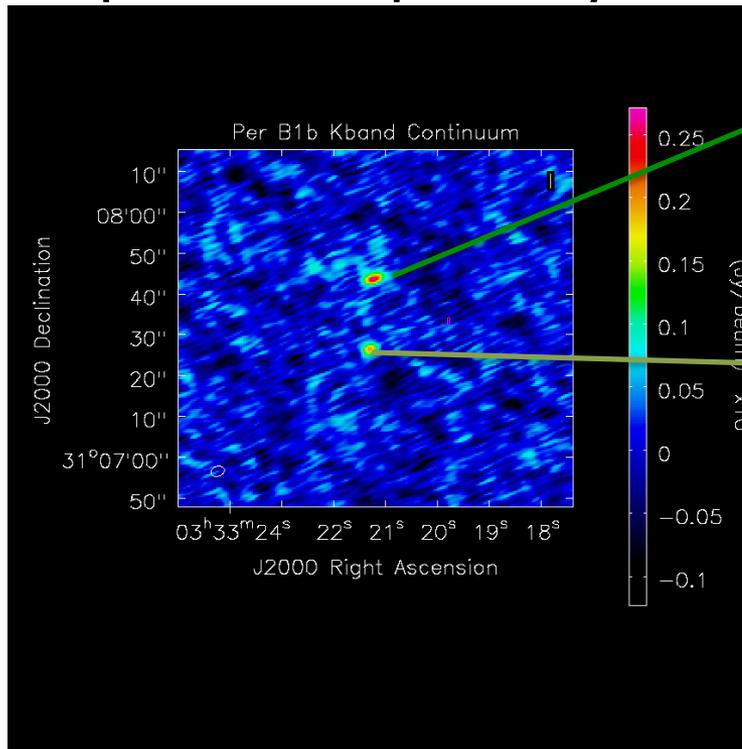

- Note atmospheric noise rise on right.

# Complex Organic Molecules (COMs)

- Note that the complex organics were only detected in B1b
- $\text{CH}_3\text{O}$ , discovered here, is a precursor to COMs
- Clearly gas-phase chemistry is active in both sources
  - Strong fractionation of D-containing molecules
  - Possibly indicated by abundance of  $^{15}\text{NH}_3$ 
    - Value is solar,  $\sim 446$ , in TMC1C.
- Gas-grain chemistry: COMs form on grain mantles during warmup phase ( $>30\text{K}$ ) followed by evaporation
  - But diffusion of radicals ineffective for  $T < 25\text{K}$ .
  - Subsequent gas phase chemistry may occur

# High Angular Resolution Constrains Emitting Region

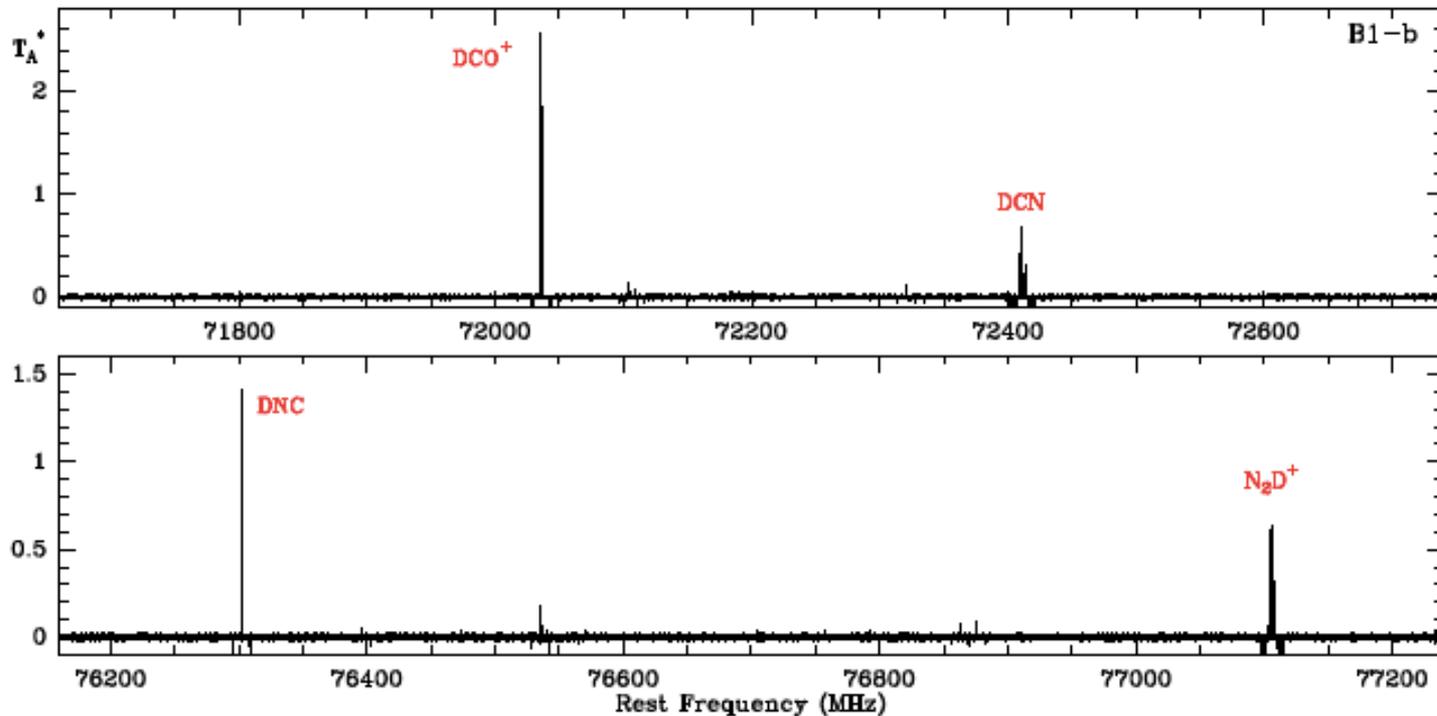

- BI-b, as noted, harbors two very protostellar objects with wimpy outflows (Gerin et al 2015)
- VLA Kband image locates the protostars precisely

# GBT Survey of B1b 67-80 GHz

Marcelino et al: follow up of IRAM survey

- N.B. IRAM beam  $\sim 30''$  encompasses whole core; GBT beam  $\sim 9''$  pointed between B1b-S and B1b-N samples envelope of both.

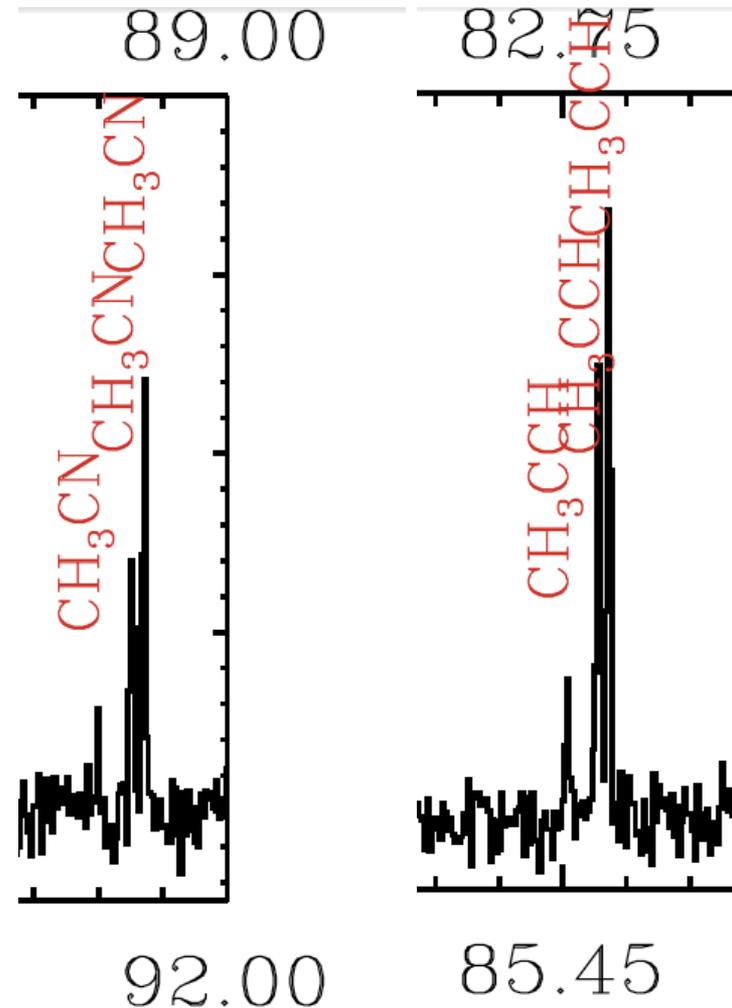

- Sensitive spectral surveys with large telescopes reveal astounding chemical complexity, can elucidate evolutionary status of protostars

# The lines are seen in cold cores

- Marcelino et al Survey of the B1b core shows emission from both 80 GHz lines at tenth K level. Temperature fit suggests  $\sim 15\text{K}$ , agrees with  $\text{NH}_3$
- $J=5-4$  and  $J=4-3$  can be observed simultaneously with other lines with broadband receivers (e.g. GBT, ALMA Band2).
- Relative intensities of different  $J$  lines provide a measure of density over a range  $10^4$  to  $10^6 \text{ cm}^{-3}$ ; they lie near excitation peak

High Frequency Science with GBT

# Summary

---

- Studies of BI clouds approaching star formation
  - Starless cores are most effectively studied with large telescopes, not interferometers
  - Onset of star formation occurs in a dense chemically depleted environment, poorly probed by some molecules ( $\text{NH}_3$ )
  - GBT beam well suited to explore depletion regions at 3mm nearby
- Rich molecular structure in the BI cores probes the evolution of the cores
  - One core has only weak outflow, may locate a FHSC
  - Second core shows stronger outflow, early star formation
  - Rich spectrum of complex organics compared to cold core TMC1
  - The COM signature may signify the onset of star formation
  - Where present, COMs may be used to probe deep core physics, to which GBT beam is well-suited
