Very Long Baseline Array

Imaging: *clean*

After calibration: Make an image!

Task: *clean*

- Grids the visibilities
- Calculates imaging weights for each cell
- Fourier Transform visibilities to dirty image
- Calculates *dirty* psf/beam from uv-coverage
- Deconvolves (cleans) data (creates a model, a residual, an image=conv. model+residual)
- Calculates *clean* psf/beam
- Applies primary beam correction if requested

Imaging: *clean*

Gridding:

- **Regular gridding** (spheroidal): single pointing
(fov < primary beam)
- **Mosaicking**: many pointings stitched together in either uv or image plane
- **W-projection/faceting**: account for wide fields/sky curvature
(fov > primary beam)
- **Outlier fields**: multiple, small sky patches

Imaging: *clean*

Gridding spectral line:

- Grid per channel/velocity/frequency interval
- Specify: number of planes, start frequency/velocity, width of each channel (can be negative)
- For gridding in velocity one also needs rest frequency, velframe (LSRK, BARY, etc.), Doppler (optical, radio) [internal: LSRK, radio]
- *clean* automatically regrids all data to the specified output frame. No *cvel* is required.
- When $\Delta v/v > 5\%$: CASA will calculate a **psf per plane**
- CASA analysis tasks can handle such beam variations
- Use **imsmooth** to bring to common beam if needed

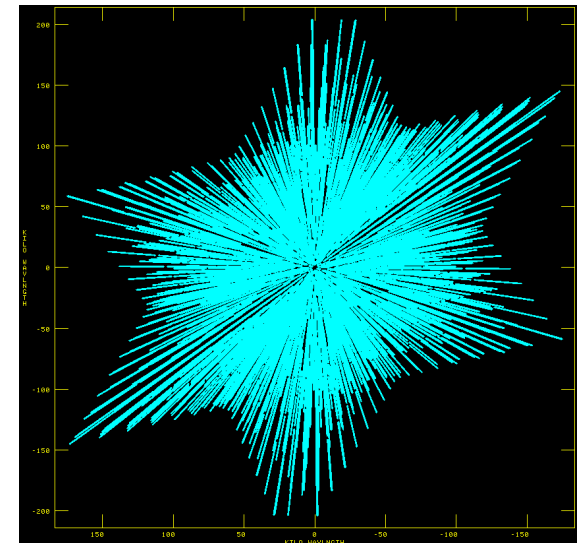

Imaging: *clean*

Gridding continuum:

- Multi-frequency synthesis
- Each visibility has a uv-coordinate that depends on the wavelength \rightarrow wide bands improve uv-coverage and therefore the image quality

Example

64MHz \rightarrow 16x64GHZ

Images: E. Momjian

Imaging: *clean*

Weighting:

- Will apply weights from visibilities *and also calculate*
- **Natural** weights ($W=1$ per visibility) creates **largest** psf (lowest resolution) but also **lowest** Jy/beam noise
- **Uniform** weights ($W=1$ per cell): best resolution (**smallest** psf) but **higher** Jy/beam noise
- **Briggs (robust)** weights is an interpolation between the two extremes
(typical best compromise: robust=0)
- **Taper** (Gaussian function of uv-distance)
- Other: super-uniform, radial, briggsabs

Images: U. Rao

-5 (uniform) ... robust ... 5 (natural)

Imaging: *clean*

Deconvolution:

`imagermode='csclean'` performs minor cycles to find components, add to model, go back to visibilities, subtract components, FT into image domain

`psfmode:`

- `Hogbom` psf subtraction on full image
- `Clark/Clarkstokes` uses smaller beam patch for subtraction, improves speed, `clark` searches in combined $I^2+Q^2+U^2+V^2$ for components, `clarkstokes` in each Stokes plane separately

Imaging: *clean*

Multi-scale cleaning

- Most cleaning algorithms assume that an image is composed of δ -functions
- Flux that is stored in large components will thus be broken up into many small components when they may be better described by fewer but extended components
- **multiscale** clean allows one to set a range of scales to be cleaned simultaneously
- Appears to reduce ‘negative bowl’ syndrome of missing short spacings
- Cleans closer to the noise and leaves less flux in the residual image
- Rule of thumb: smallest scale (in units of pixels): 0 (for point sources), largest scale: \sim half of the target size, then a few in between (advise: `im.setscales`)
- `Smallscalebias`: control the tendency to pick smaller scales

Rich et al. (2008)

Imaging: *clean*

Wideband cleaning MSMFS (multiscale-multi-frequency):

- Fits wideband model to dataset, spatially and spectrally
- Spectral index can be expressed via Taylor-term expansion

$$I_{\nu}^{\text{sky}} = \sum_t I_t^{\text{sky}} \left(\frac{\nu - \nu_0}{\nu_0} \right)^t$$

- t , the number of terms can be chosen with *nterms* parameter
- The equations can be rewritten to provide
 - Spectral index with *nterms*=2
 - Spectral curvature with *nterms*=3

Imaging: *clean*

Wideband cleaning MSMFS:

- Example: A2256

Intensity

Spectral Index

Images: F. Owen

Continuum Imaging: *clean*

Wide-band wide-field imaging

- Primary beam also varies with frequency
- Steepening of spectral index towards edge of beam
- **widebandpbcorr** will apply primary beam correction to Taylor terms (including flux, spectral index, curvature, ..)
- (regular primary beam correction: **imbpcor**)

Imaging: *clean*

Mosaicking

- Combine multiple pointings on the sky
- 3 basic methods:
 - Image and clean each pointing separately, then combine
 - → **linearmosaicking (lm)** Tool
 - Image separately, then perform a combined deconvolution (`imagermode='mosaic' ftmachine='ft'`)
 - Combine in uv-domain, FT, clean full mosaic (`imagermode='mosaic' ftmachine='mosaic'`)
- Images still require primary beam correction (**impbcor**) using `image.pbcoverage`

Imaging: *clean*

W-projection

- W-projection is a method to correct for non-coplanarity of the sky (regular imaging assumes it is flat)
- Needed for fovs $>$ primary beam or
(λ : wavelength, B: baseline length, D: dish diameter) $\frac{\lambda_{\max} B_{\max}}{D^2} > 1$
- **Faceting**: describes the sky curvature by many smaller planes
- Number of facets:

$$N_{poly} \approx 2\theta_{FoV}^2 \frac{B_{\max}}{\lambda_{\max}}$$
$$= \frac{2B_{\max} \lambda_{\max}}{[fD]^2}$$

Example:
VLA A-config
1.0GHz
 $N > 34$

$f=1$ for critical sampling.
 $f < 1$ for high dynamic range

Imaging: *clean*

Outlier Fields

- When sources are outside the image but are bright enough to throw sidelobes on the main field, they need to be cleaned
- To be cleaned, they need to be imaged, but the required images could be very large
- Solution: **outlier fields**
 - User provides positions of those sources (e.g. from all-sky catalogs)
 - Clean will cycle through all fields and subtract the part of the psf that is observed in each field
 - May need to set a large threshold to begin to clean outliers first

Imaging: *clean*

Images produced

- **Imagename.model** (clean components in Jy/pixel in a cube)
- **Imagename.residual** (residual image after all components are subtracted; Jy/dirty beam)
- **Imagename.image** (model x clean beam + residual; expressed in Jy/clean beam)
- **Imagename.mask** (mask)
- **Imagename.flux** ([mosaicked] normalized sensitivity map / for single pointing: primary beam response)
- **Imagename.pbcoverage** (mosaicked primary beams per pointing, use for impbcorr)
- Restarting clean with same imagename will continue cleaning where it left off (if parameters such as image and cell size match)
- To start a new clean remove old files first with **rmtables("imagename.*")**
(rm -rf may keep images in memory)

Imaging: *clean*

Clean tips:

- Clean is writing the model data to the MS. This can be done either as an image (*usescratch=F*) or directly as visibilities (*usescratch=T*)
- Try to **avoid CNTRL+C** while cleaning. When the model is being written to the MS but interrupted, it can corrupt your MS!
- Some image sizes will compute faster than others, sometimes even larger ones. Rule of thumb for good *imsize* is 10×2^n (but clean will suggest good *imsize* when bad numbers are being used)
- Choose a pixel (*cell*) size that is at most $\sim 1/4$ the size of the psf minor axis
- dirty image: *niter=0* (*niter=1* if you want a clean beam)
- If you need a model convolved with clean beam, subtract the residual from the combined image

Imaging: *clean*

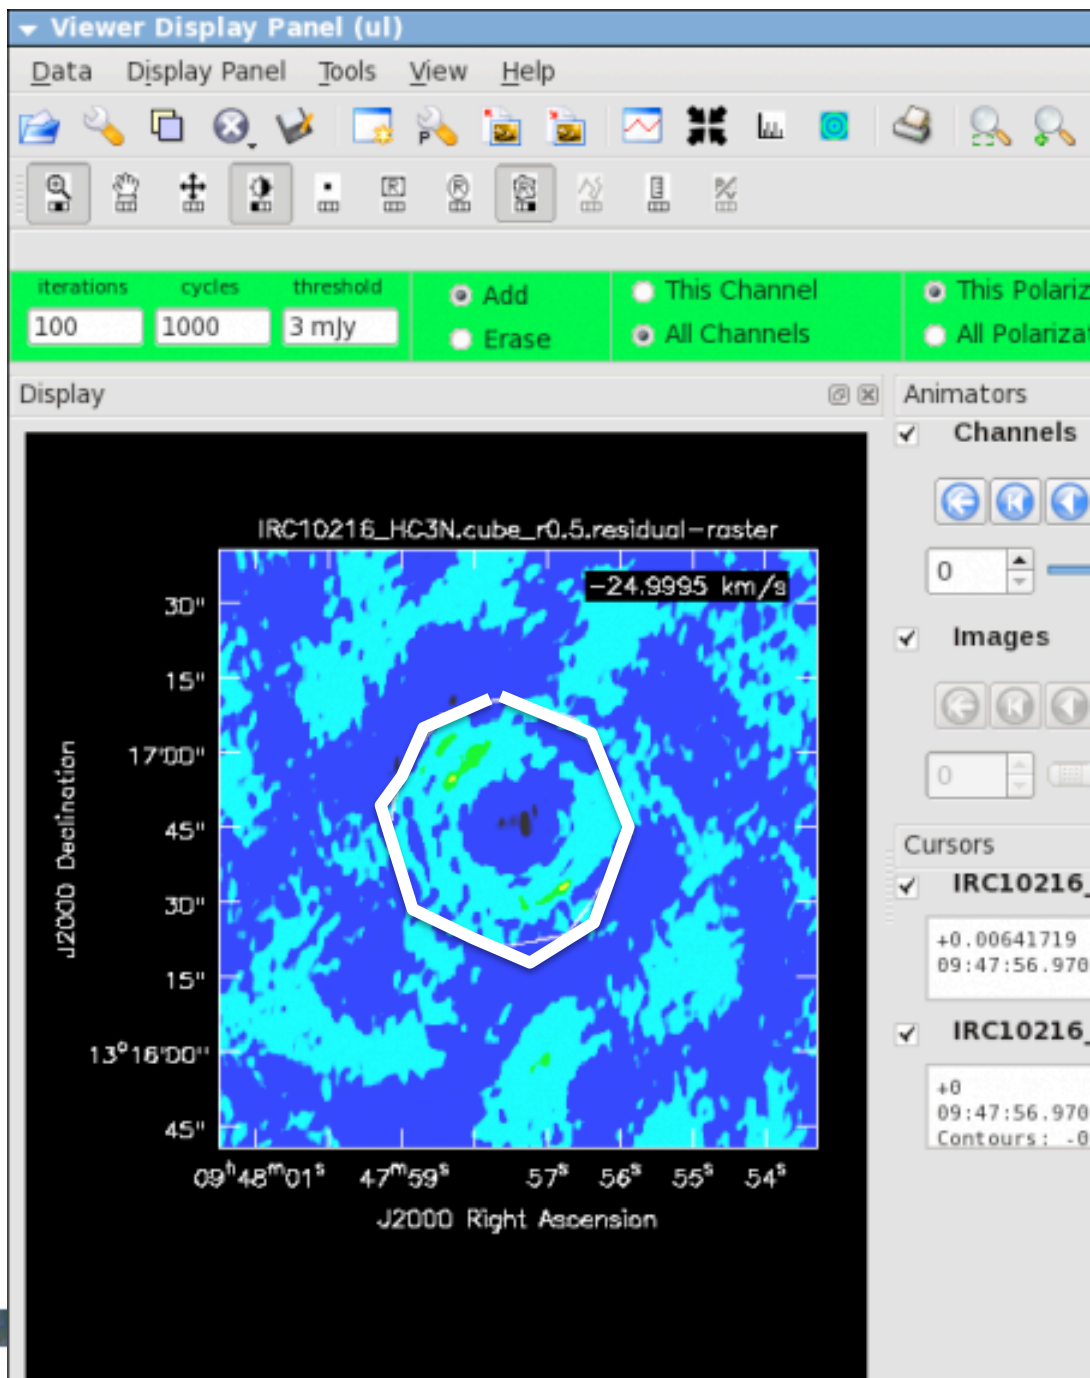

Clean tips:

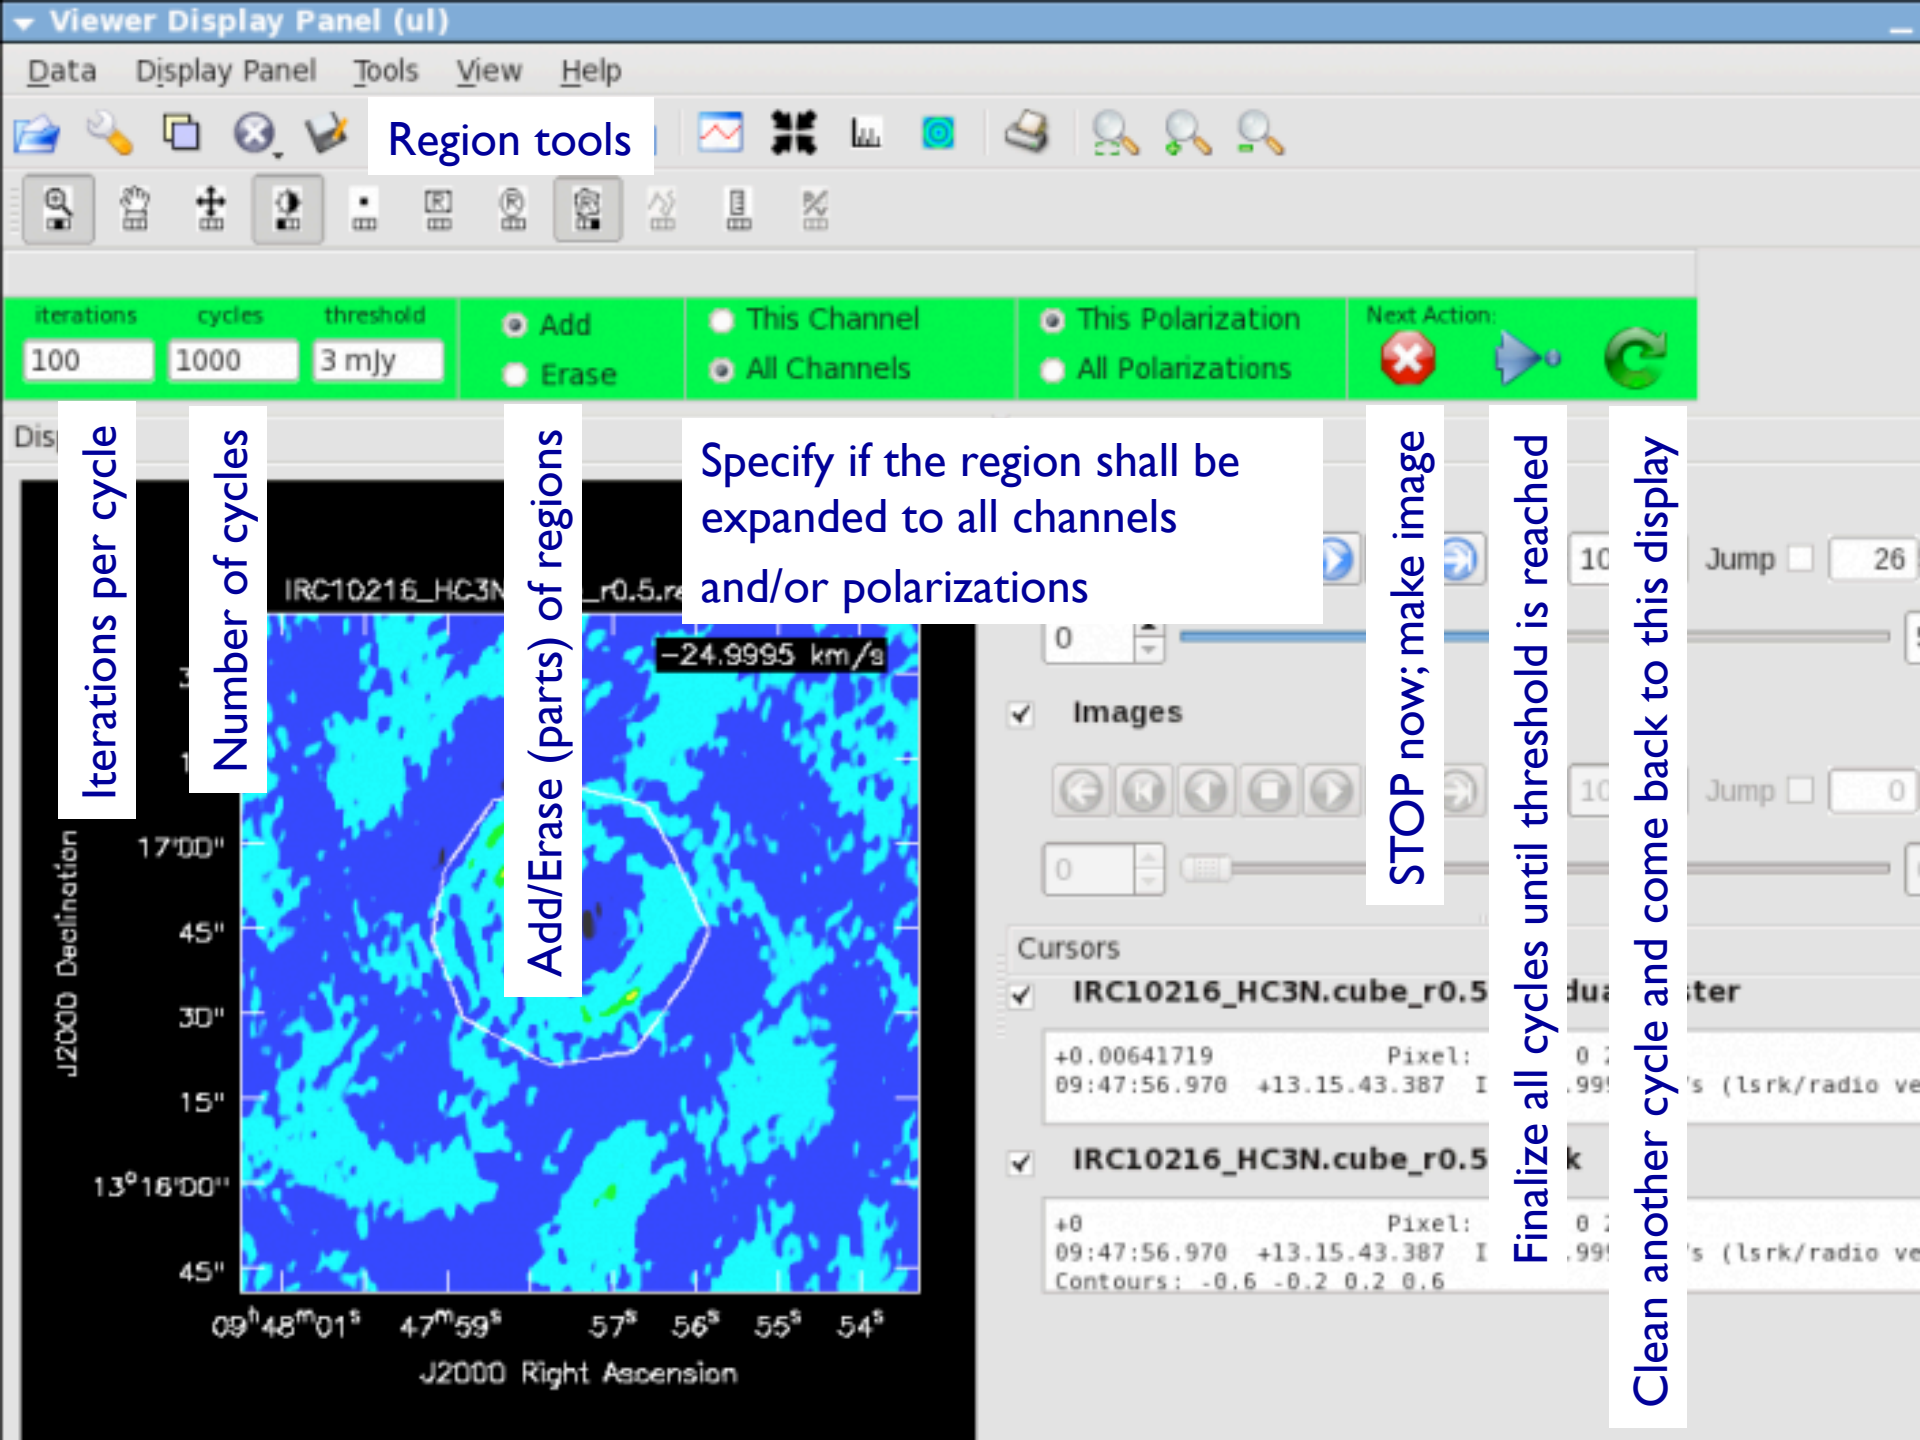

- The CASA logger will report *cleaned and residual peak fluxes*. Good cleaning will increase the cleaned flux and decrease the residual peak. When the numbers oscillate, you may have cleaned into the noise, stop beforehand
- Clean threshold will prevent deep cleaning into the noise (typically used $\sim 2.5\sigma$); use high *niter* so that the threshold limits the cleaning
- An FFT of the image (*ia.fft* tool) can be used to assess how well clean performed. A good clean should interpolate well between measured uv-points
- Mosaicking (Ekers-Rots theorem) and multiscale both help to reduce the missing short spacings issue/negative bowls
- Note that your residual has units of $Jy/[dirty\ beam]$ and your model x Beam $Jy/[clean\ beam]$. Apply flux corrections if needed (Jörsäter & van Moorsel 1995)

Imaging: *clean*

interactive=T cleaning

- Invokes the viewer with the residual image
- Cleaning regions (masks) can be made for each spectral channel if needed
- If no mask is specified, cleaning is *not* performed (only in interactive mode)

Imaging: *tclean*

tclean is an improved *clean* task.

- more logical interface
- additional parameters such as options to write output files
- Parallelization (both continuum and spectral line)
- AW projection: correct for W-term and also for beam rotation on the sky (A-projection)
- *nterms* > 1 for mosaics
- Hooks for autoboxing algorithms
- Outlier field flexibility (e.g. different gridding,, *nterms*)
- Better output (includes theoretical rms)

Image/Data combination: *clean+feather*

To combine VLA arrays:

- run `statwt` on each dataset to adjust the weights
- *Clean* the datasets together

To add single dish (make sure the SD header complies, in particular it has to be in units of Jy/beam):

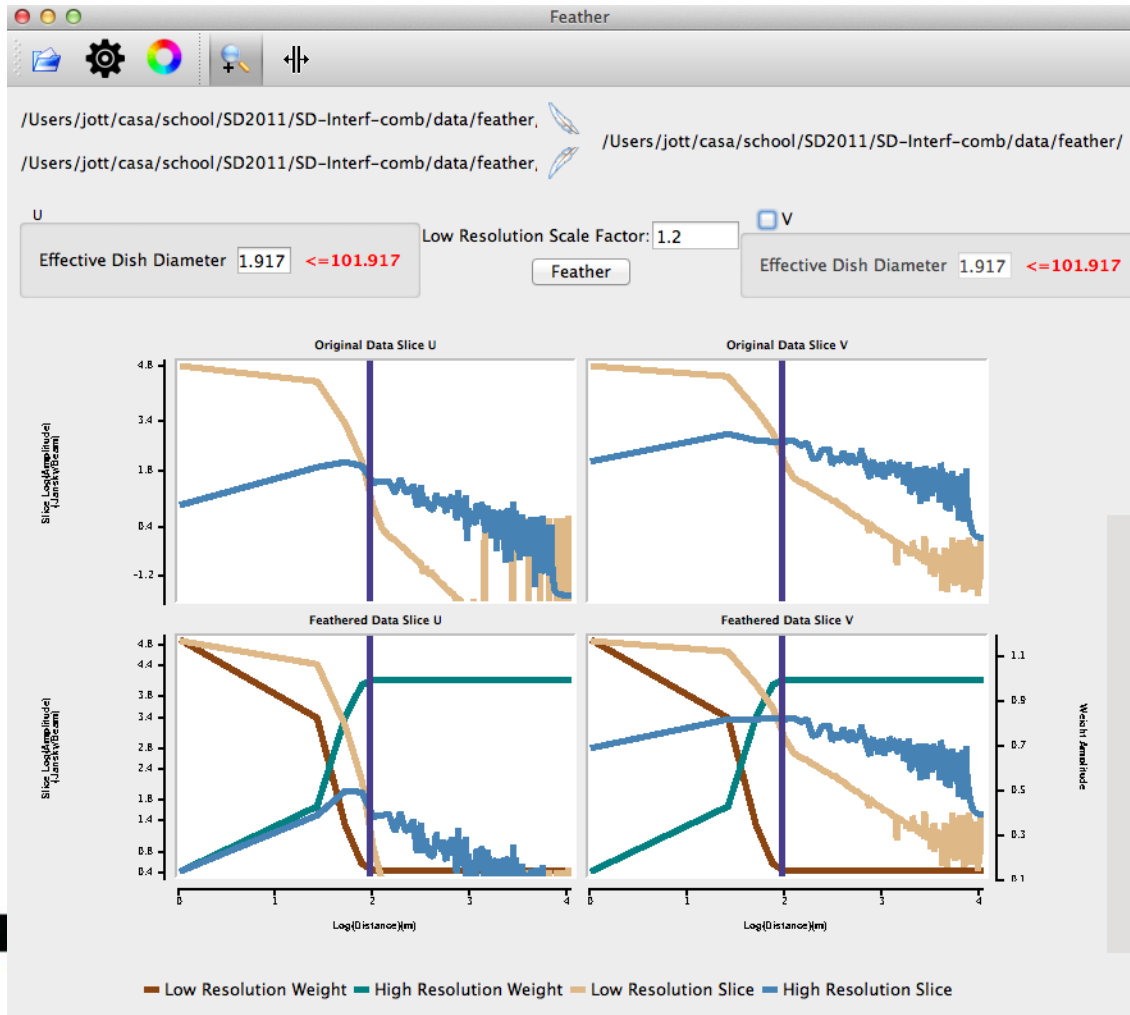

- Use SD image as *modelimage* in *clean* to be a starting model for interferometric data, the model retains short spacings from SD image
- Use *feather* (or *casafeather* GUI) to combine a high-resolution image (typically interferometric) with low-resolution image (SD) in the Fourier domain
- SD data will define the total flux of your image and remove negative bowls

Image/Data combination: *clean+feather*

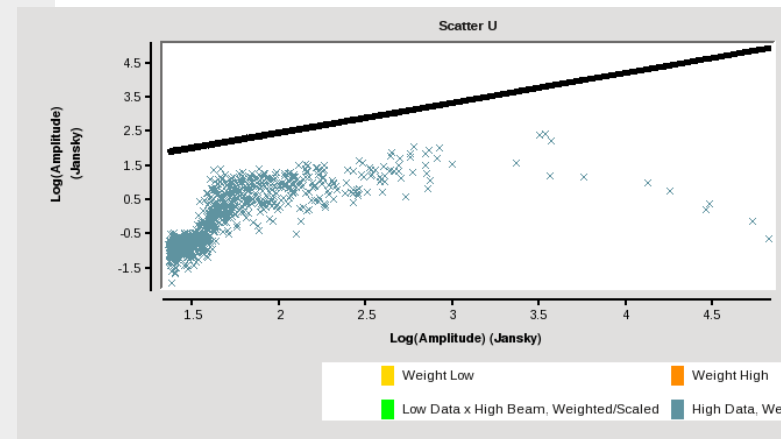

Image combination

Example feather

Works in *Fourier domain*

- FFT SD, apply PB(SD) as weight
- FFT *cleaned* interferometric image, apply $1 - \text{PB}(\text{SD})$ as weight
- Adjust calibration differences
- Add
- FFT^{-1}

Image/Data: *clean+feather*

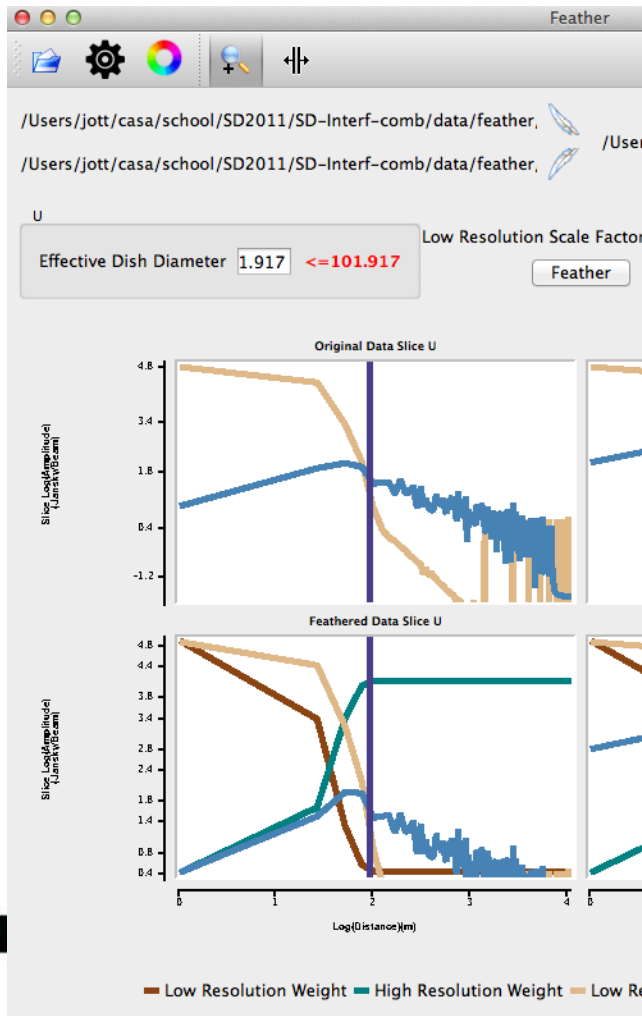

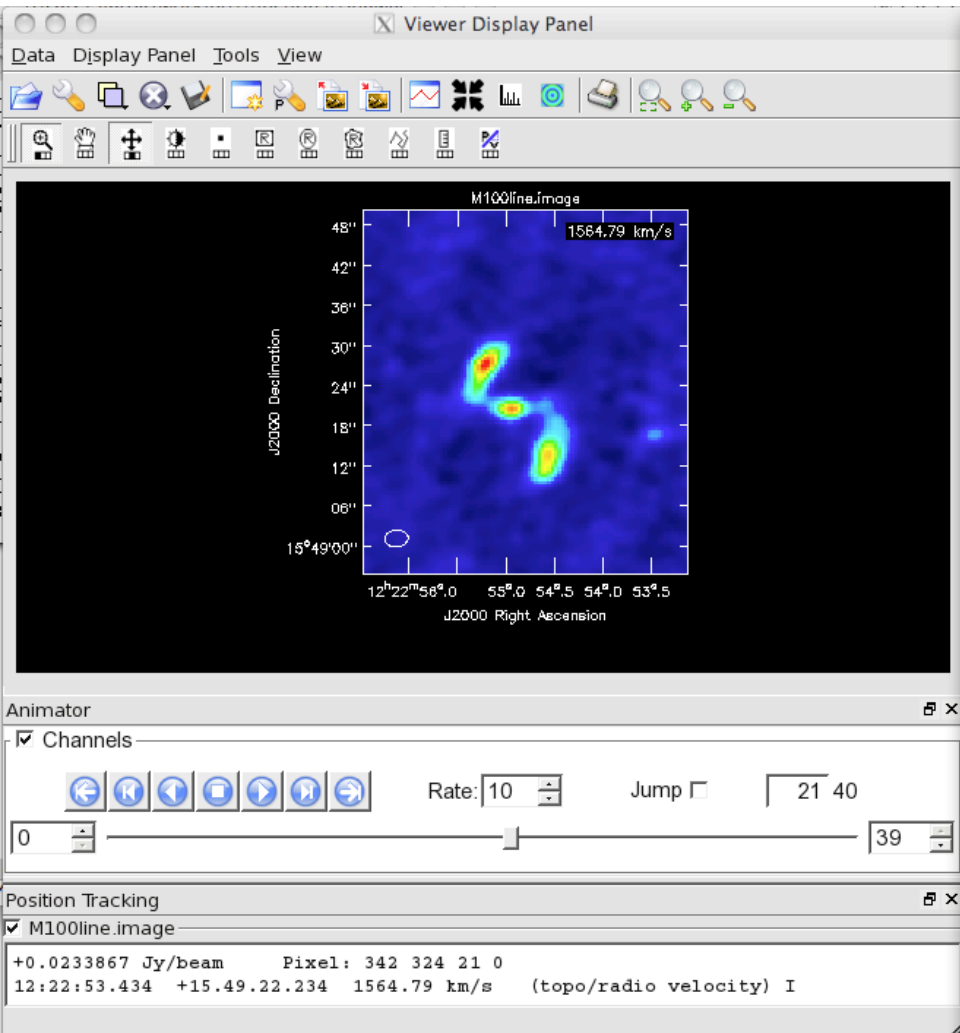

Image Viewer

The screenshot shows the 'Data Manager -- Viewer' window. It has a 'load' button and tabs for 'save image' and 'save region'. The 'directory' field contains '/lustre/naasc/aleroy/casa_test/reference_images'. A list of files is shown, with 'M100line.image' selected. To the right, 'loading options' are displayed in a table:

loading options	
shape	restoring beam
600, 600, 40, 1	3.51", 2.48", -85.64"
J2000 right ascension	J2000 declination
12:23:05.292, 12:22:44.504	+15.46.39.985, +15.51.39.985
frequency range	velocity range
114.588, 114.74 GHz	1778.13, 1381.93 km/s

Below the table are four buttons: 'raster image', 'vector map', 'contour map', and 'marker map'. At the bottom, there are 'update', 'leave open', 'LEL', and 'close' buttons.

Image analysis

Image analysis tasks can frequently performed in both, a task or in the viewer, these tasks also accept changing psf per plane.

- **immoments**: create moment maps of spectral cubes
 - includes:
 - integrated intensity (moment 0)
 - intensity-weighted mean velocity (moment 1)
 - intensity-weighted velocity dispersion (moment 2)
 - plus many other modes like peak intensity map, median, etc (which are mathematically not moments)
 - Can exclude some pixel ranges
 - Can calculate many moments in one execution

Image analysis

- **imcontsub**: image-based continuum subtraction
 - Calculates continuum per pixel through a polynomial
 - Subtracts from image
 - Creates a continuum and a line-only image
- **immath**: mathematical operations on images
 - Calculates any mathematical expression, e.g. $IM0 + \exp(IM1 * 200)$
 - Has modes to calculate spectral index, polarization position angle, polarized intensity images
 - Uses *LEL* language:
 - Mathematical expression on images
 - Also used for thresholds (e.g. 'IM0 > 0.1jy')
 - Boolean operators (e.g. 'IM0 > 0.1jy && IM1 != 0')
 - Conditions (e.g. 'IM0 [IM1 > 0.1jy] / IM1')
 - Special functions (e.g. SPECTRALINDEX, amp, ..)

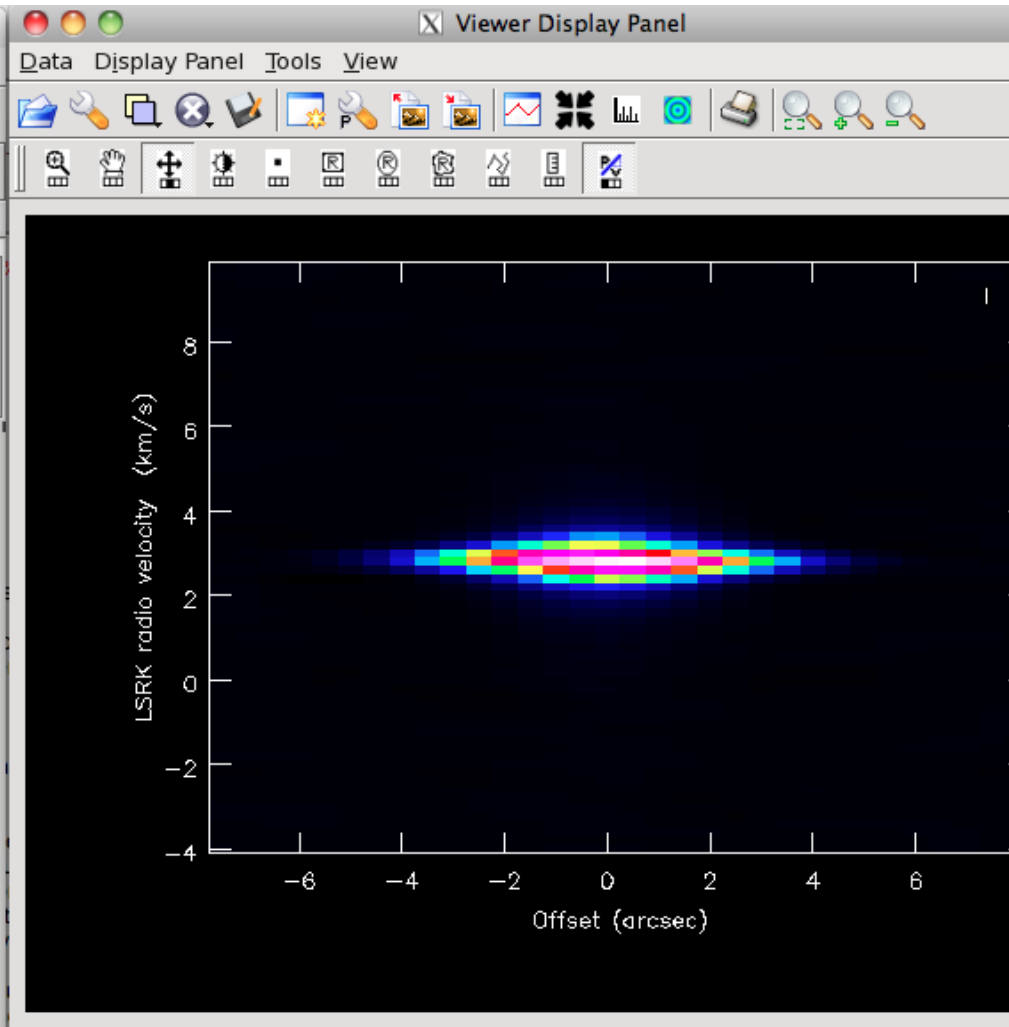

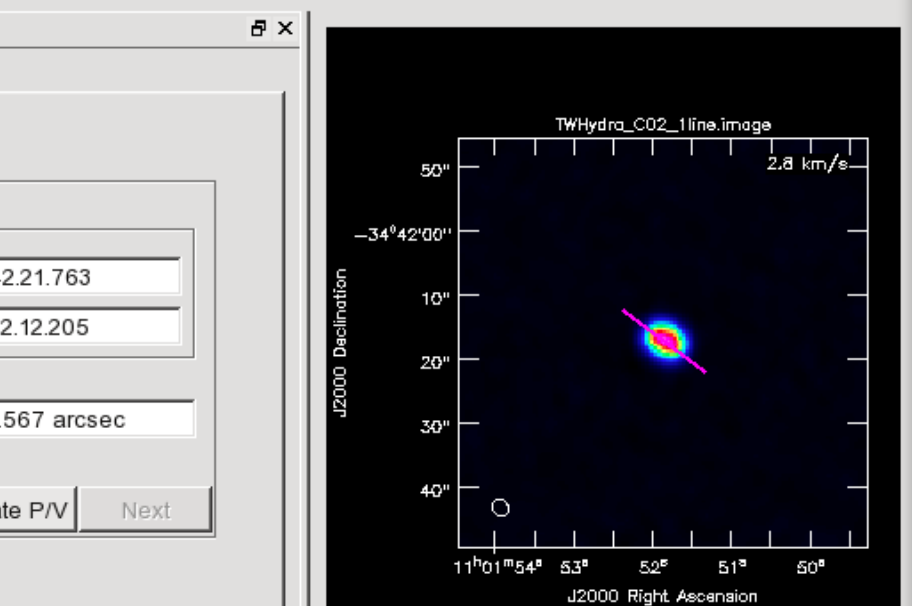

Image analysis

- **impv**: Position Velocity diagrams

Viewer Display Panel

Rate: 10 Jump 34 70

69

Position Tracking

TWHydra_CO2_1line.image.pvline.001

Image analysis

- **specfit**: fits 1-dimensional Gaussians and/or polynomial models to an image or image region, typically along the spectral axis
 - Can fit multiple Gaussian multiplets with constraints
 - Can be per pixel \rightarrow images of amp, fwhm, center velocity for each Gaussian component

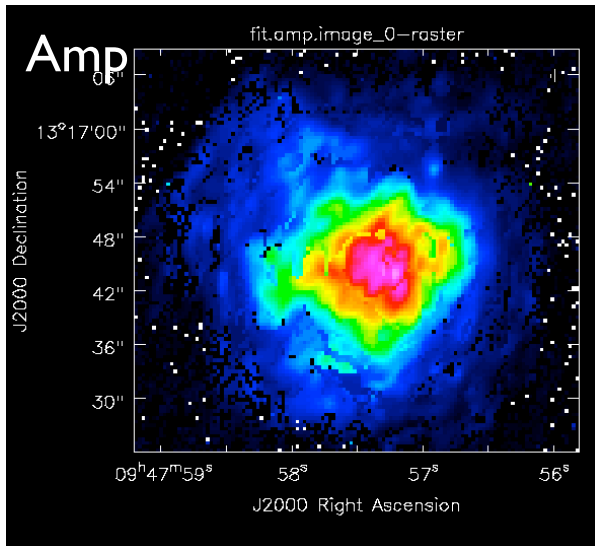

Image analysis

- **imfit**: fit one or more spatial elliptical Gaussian components to sources
 - **ia.findsources** can be used for source detection
- **imstat**: image statistics, many robust methods are available
- **imregrid, imtrans, imreframe**: transform image coordinates spatially and spectrally
- **imrebin, imsubimage**: change image/pixel size
- **rmfit, spxfit**: calculation of rotation measures and spectral indices
- **imval**: dump out the data into a python dictionary

- Many image analysis tasks return python dictionaries, use as
 - **data=imval('image')** to assign the python dictionary output to a variable (here: 'data')
- Use the power of python! Once the data is available as a python dictionary only the sky (well, the universe..) is the limit of your data analysis!
